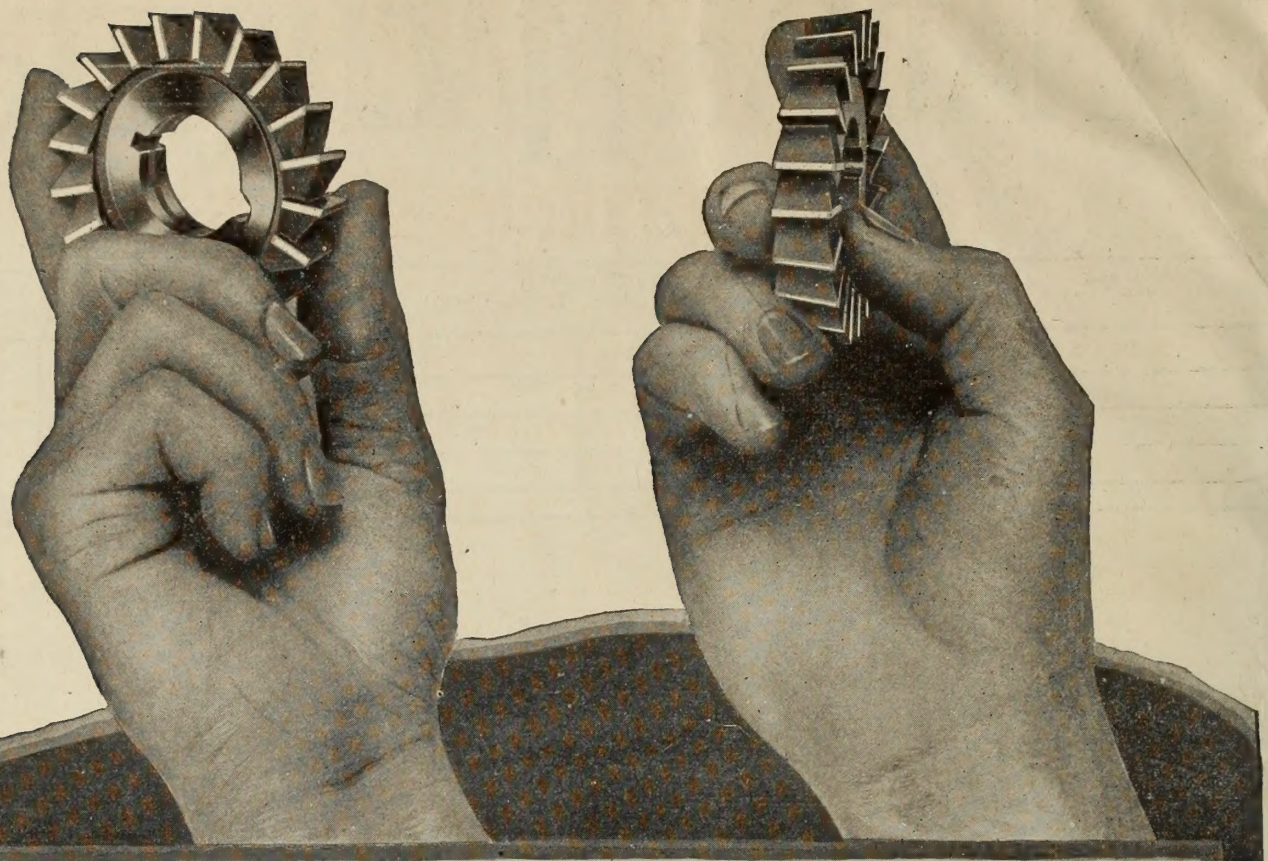
Throw Away Files —not Time

WHEN you use a file that has become dull, you are wasting time.

To give efficient service, a file's teeth must bite keenly at every stroke.

Throw away that dull file and get a new one. Files cost less than labor.

Maximum service from every file is ensured if you specify one of these brands:



KEARNEY & FOOT — AMERICAN
GREAT WESTERN—ARCADE—GLOBE

FILES AND RASPS

Made in Canada by:

Nicholson File Company

PORT HOPE - ONTARIO

If it's speed you need--

One trial will prove the advantage of Pratt & Whitney Milling Cutters. No matter what the nature of the work they will give you the highest production the machine is capable of.

They're designed for free, fast cutting. And tempered and seasoned to last longer.

PRATT & WHITNEY MILLING CUTTERS

Ask us for prices and details on Plain Milling Cutters, Side Milling Cutters, Inserted Blade End and Side Cutters, Screw Slot Cutters, Coarse Tooth Side or Plain Milling Cutters, Involute Gear Cutters, Concave, Convex and Double Angle Cutters, Cutters for Spiral Mills, Roll Thread Die Hobs, Key-Seating and Slotting Cutters, Straight and Spiral Cut End Mills (B. & S. and M. T. Shank), Spiral and Straight Shell End Mills, etc.

And we make formed cutters for special work also. All are backed by the guarantee for goodness that the P. & W. trademark indicates.

D.K.McLaren's

GENUINE BRITISH-OAK TANNED

LEATHER BELTING

TRADE MARK

The oak leaf is the sign to go by

Bear the oak leaf in mind the next time you are buying belting—it will guide you to better belt service.

A leather belt will transmit 25% more power than the same sized belt of other material.

D. K. McLaren's Leather Belting is just as good as we know how to make it. Only the **backs** of the choicest steers are used. They are skillfully, Genuine British Oak tanned by experts and all stretcher ends cut off before they are made up into belting.

That is why D. K. McLaren's Belting is **cheap!** Why it saves its users a remarkable amount of power, time and labor. Why it is as serviceable as a leather belt can possibly be.

To Decrease Operating Costs

The side carriage is an important part of the W.& S. turret lathe. It reduces operating costs, often by as much as one-half. It operates simultaneously with the turret and independently of it. The side carriage has a separate feed rod.

Take some of the simplest bar jobs; by cutting off with the side carriage while the turret tools are finishing their work, you save most of the cutting off time.

Here is the picture of a W.& S. 2-A. in a railroad shop. This machine makes bolts, pins, oil cups, valve parts, piston rods, and many other parts used in the repair of locomotives and cars.

On all these parts both turrets operate together.

Take this feature and the fact that the machine operates easily and accurately, and you know why the machine is popular with the shop men. It delivers the goods.

Send us blue prints of your parts and we'll tell you how long it will take to do your work the W.& S. Way.

TRADE MARK
BRISTO
REG. U. S. PAT. OFFICE
PATENTED SAFETY SET SCREWS

SET A NEW STANDARD

The distinctive dove-tail slots or flutes of the "Bristo" safety set screw are one of the features which put "Bristo" in a class by itself. "Mushrooming," for instance, is impossible, and splitting or cracking have been removed from the list of your manufacturing worries. As the wrench turns, the unique "Bristo" design contracts the screw; on releasing the pressure the screw tends to expand—a tremendous gripping factor.

THE JOHNSON FRICTION CLUTCH

The Case Against the Countershaft

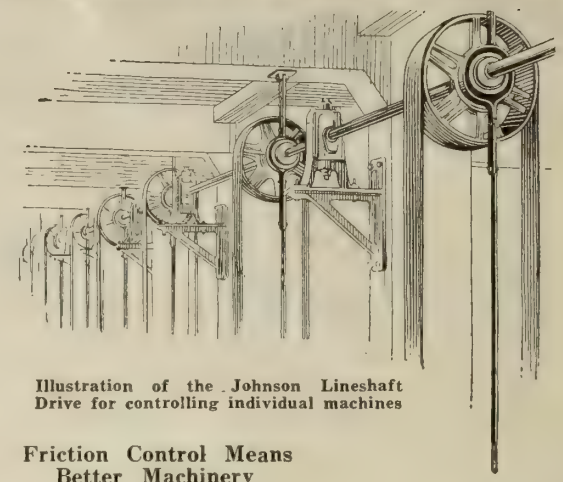
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.



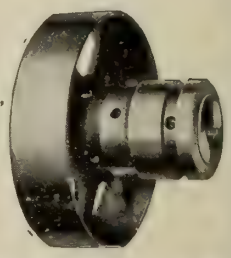


Illustration of the Johnson Lineshaft Drive for controlling individual machines

Friction Control Means Better Machinery

Whether it is applied overhead or in the machine itself.

FORD-SMITH

Grinders

Quality and Quantity!

THERE are difference in grinders. Differences that make it worth your while to consider carefully which grinder you will buy.

Ford-Smith Grinders have established a reputation for quality as well as quantity. They have proven their ability to do quicker, better, more satisfactory work and at the same time keep costs down to the minimum.

There's a size of Ford-Smith Ginder to meet every grinding need. The line consists of Motor Drive Grinders, Floor Grinders, Disc Grinders, Water Tool Grinders and many others.

Suitable grinding equipment may be the means of saving you a considerable sum during a year. One of our engineers will be glad to put it down in black and white.

Let us furnish full information.

ROYLITE
CLEANER

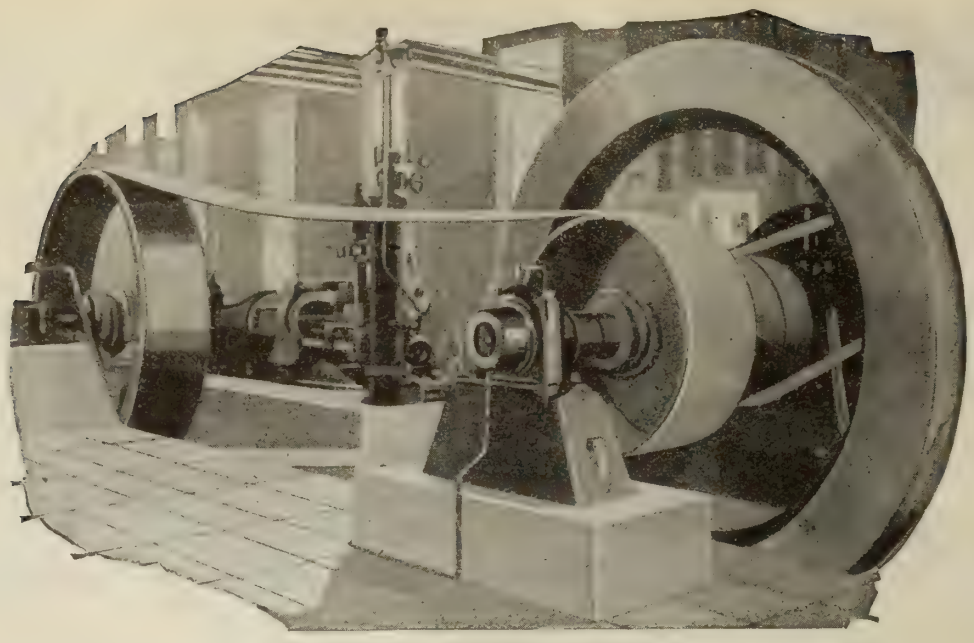
Roylite Giving Good Results in a Hamilton Plant

In above illustration (drawn from actual photograph) is seen the cleaning of Die Castings with *Roylite Cleaner* This operation is performed before the castings are plated. and was difficult because the heavy oil and grease on work could not be cleaned effectively without discoloring the soft metal. *Roylite* proved very successful and removed every particle of grease and dirt without injuring the metal. It is doing it quicker and more economically than any other solution has ever done it before. The head plater here says *Roylite* is the best solution he has ever had.

In this case the castings are immersed for three seconds in *Roylite Cleaner*. Only four ounces of *Roylite* are required to the gallon and very little extra cleaner is required to keep the solution up to required strength.

Roylite works equally satisfactorily on Brass, Steel, Copper or any other metal.

Roylite Cleaner lasts longer, works quicker and costs less—prove it to your own satisfaction with a trial order. Sample sent on approval. Our experts give free demonstration.



Write for Booklet. ***Put up in 500 lb. Barrels.***

Made In Canada

Machining Delco Generator Frames

The photograph above shows a tool set-up on a Steinle 24-in. Turret Lathe for turning out Delco Generator Frames at the plant of the Delco Light Company of Dayton, Ohio.

The chucking fixture revolves in a steady rest and is equipped with centering and stop pins for centering and locating rear end of frame by pulling sleeve collar forward. Set screws hold the front end in place. The turret fixture is reinforced in the machining operation by the overhead bar support; thus preventing undue chatter or jar under the heavy cuts taken.

This is only one of a number of installations in plants manufacturing electrical equipment where the Steinle is called upon to produce various parts from castings, forgings or bar stock.

In view of present manufacturing conditions it is invariably performance that counts and the Steinle qualities of accuracy, speed, ease of operation, power, reliability and economy of upkeep are guarantees of satisfactory performance on your own work.

Material—Cast Steel

Finish—Bore, Counterbore, Face Bottom, Face Lugs

Time—25 Minutes Each

Why not send us your blueprints if your requirements call for the installation of equipment of this character? We shall be glad to furnish you with production and tooling estimates, or to have a qualified representative call and take up the question of Steinle methods as applied to your production problems.

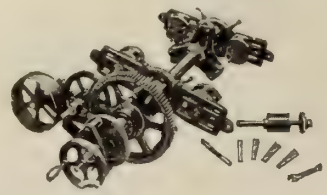
PIPE CUTTING and THREADING

The Landis is Liked Instead of Tolerated

There are some tools and machines you will put up with in spite of the fact that you are disappointed in their results. You know how it is---good machine as any others in your plant but not just what you were looking for. You tolerate it because you can use it. But you wouldn't buy a second machine.



When you like a machine you are sold to that machine. It's the machine you are going to consider when you find it necessary to increase capacity.

Landis Pipe Cutting and Threading Machines are the kind of tools you can't help liking---the machines you buy again. The Ford & Kendig Co., Philadelphia, installed these Landis, herein illustrated, three years ago. To-day they are using three of the same type for cutting and threading 6-in. wrought steel pipe.

"Morse" is the Guarantee Always Behind the Efficiency, Durability and Service

Small Machine Shops, Auto Repair Shops Welding Companies

Do you want a business like this?

A day's work laid out at the repair shop of Geo. H. Woodwards, San Francisco

Opportune Time

There is no business to-day that has the possibilities and which fits so nicely into a small machine shop, automobile repair shop, or a concern doing welding, as the regrinding of worn or scored cylinders.

Many companies would have had to close their doors this Spring but for the business obtained through regrinding. It does not require skilled mechanics for operators, and the profit received on the capital invested is unusually large.

The Field for Regrinding.

There were over 9,000,000 commercial and pleasure cars registered during last year. Truck and tractor cylinders require attention once a year. Passenger cars should be looked over at least once every two or three years. Figure out for yourself what your chances are with only approximately 350 concerns properly equipped for such work.

Consider also the fact that three 4-cylinder blocks a day will bring profitable returns.

Advantages to the Automobile Owner.

Reground cylinders fitted with new pistons and rings will give the motor as much, if not more, power and pep than when it was new. It cuts the oil and gas consumption in two and stops all excessive smoking.

Necessary Equipment.

Eighty-four per cent. of all pleasure cars, and ninety-one per cent. of all commercial motors manufactured are ground, and Heald Machines are used exclusively. The Style No. 55 is built expressly for regrinding work. It is simple, moderately priced, self-contained, and has a very large capacity and range, easily taking care of singles, doubles, four and six en bloc cylinders.

In addition, to handle the work satisfactorily, one should have a small lathe and drill press, bench and hand tools. A small external grinder would be convenient for finishing pistons, thus enabling the shop to purchase semi-finished pistons and grind them to the oversize required.

Now is the logical time to get started. If you want figures, in addition to the above facts, write, wire or 'phone

The Heald Machine Company

GTD HELIX

July 1921

Published Monthly by the

GREENFIELD TAP AND DIE CORPORATION

Sales Promotion Division

The following article comprises important information for all users of screw threads. Similar articles appear monthly in the GTD Helix. Isn't this service worth 25 cents for a year's subscription? Send your quarter now (stamps, if you like).

The Folly of the Full Depth Thread

Do you know that a common nut drilled out so that it contains only 50% of a full depth thread will break the bolt before it will strip, or that a full depth thread is only 5% stronger than a 75% depth thread, yet requires three times the power to tap?

We honestly believe that a majority of tapping troubles, tap breakage and spoilage of work can be laid at the door of ignorance of the proper tap drill size. We have encountered tapping operatives actually forcing taps to *ream* as well as thread the hole. That is, using a tap drill smaller than the root diameter of the tap itself and then wondering why the taps broke or would not stand up for more than a few holes, or why the work didn't run "to size."

Perhaps the operator becomes annoyed because his belt slips and causes the tap to chatter and spoil the work, or the spindle bearings require too frequent adjustment; or possibly he figures the company is too stingy to buy him a good cutting lubricant.

The use of too small a tap drill does cause all of these troubles and many more that are not always immediately traceable to it, and the average workman does not stop to analyze these effects to discover where the fault really lies. If he has trouble he waits for the "fixer" and chafes because his earning ability is impaired.

Considered from the manufacturers' standpoint the choice of the proper tap drill for each threaded hole is of far greater importance than might at first seem to be the case. It frequently makes the difference between "immediate delivery" of a product and delivery in the distant future. Increasing the depth of thread over the minimum required for strength, hinders production to a very great extent, raises the tapping cost out of all proportion to its value, and adds but a trifling amount to the strength of the part. Only in a very few instances is it necessary or desirable to have a full 100% depth of thread, and then only under advisement after the situation has been diagnosed by a Threading Specialist of recognized standing. If manufacturers in general will give more consideration to the specification of the proper drill size for tapping operations indicated on their drawings, they will anticipate and prevent any number of manufacturing difficulties they would otherwise encounter.

Some of the more progressive manufacturers have taken advantage of the opportunity to obtain expert advice by sending for a GTD Threading Specialist. These GTD Specialists are men of broad experience, and are competent to analyze and recommend threading equipment and shop practice for a single operation or to lay out and design tools and gages for a complete product.

In order that engineers, draftsmen and machinists may have always before them the approved tap drill sizes for each size of thread ordinarily used in Canada and the United States, SAE, or A. S. M. E. (Machine Screw) standards, the Greenfield Tap and Die Corporation has prepared for distribution, small pocket charts containing this information. These will be sent free to any address upon request.

To superintendents, works-managers, foremen or other factory executives who are interested we will be glad to mail larger charts containing similar data and suitable for hanging in each department for ready reference by workmen using drills and taps.

Whether you happen to be the "Super" or a machinist, an engineer or a draftsman, the little coupon in the corner filled in with your name and address and mailed to GTD Corporation of Canada, Ltd., Galt, Ontario, will bring you by return mail a GTD Tap Drill Chart. No obligation involved. Send for yours to-day.

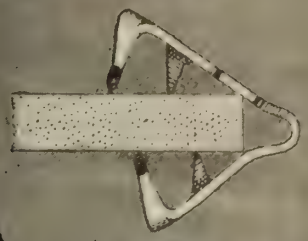
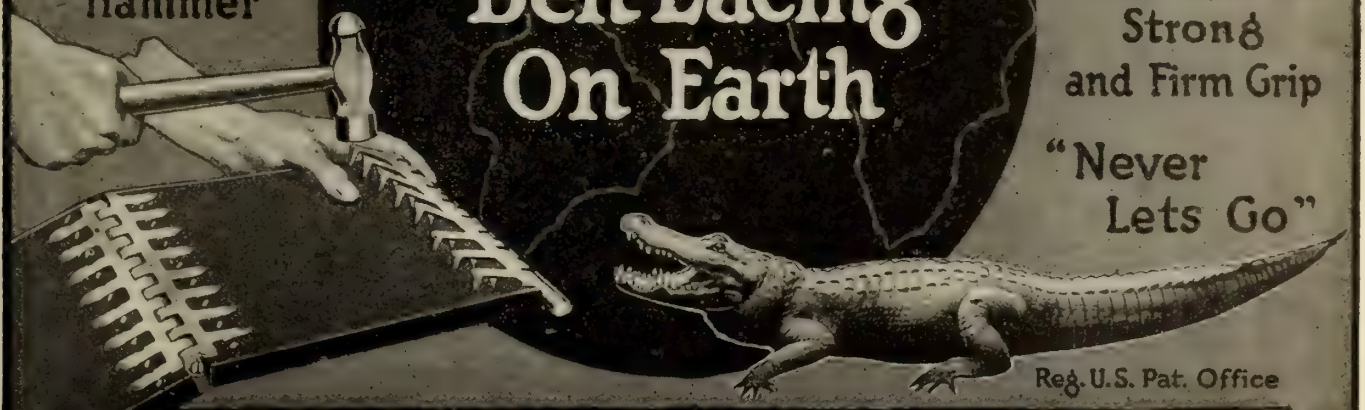
ALLIGATOR



TRADE MARK REG. U.S. PAT. OFFICE

STEEL BELT LACING

Best for Every Type of Belting



Nothing Needed But a Hammer

The Strongest Belt Lacing On Earth

Double Staggered Teeth Insures Strong and Firm Grip

"Never Lets Go"

Reg. U.S. Pat. Office

Jobbers—Dealers

Sell Satisfaction and Economy When They Sell ALLIGATOR Steel Belt Lacing

Go over these features that make "ALLIGATOR" the best belt lacing proposition for you and for your trade.

First: National and local advertising in carefully selected general publications, trade papers and consumer class publications interests all belt users and creates a demand that has been growing for twelve years.

Second: ALLIGATOR is preferred by Master Mechanics in every industry all over the world for its ease and facility of application, long life in operation, belt saving characteristics and economical features. The decision of hundreds of thousands of belting users should influence you to stock it.

Here are other reasons:

ALLIGATOR is the most easily and quickly applied of all belt lacings. **Only a hammer needed and three minutes average time** to lace a belt. Anyone can put it on.

Besides this important feature, this belt lacing has proven the strongest and consequently the **most efficient** in every test.

It outlasts any other type of belt lacing—and **saves the belting.** See illustration and note how the staggered teeth penetrate without injuring the belt and clinch down flat. Also note the sectional steel rocker hinge pin which makes a flexible hinge joint that hugs the pulley, is no thicker than the belt, and permits belt to be run on both surfaces.

In addition the use of ALLIGATOR Steel Belt Lacing is the most economical manner of taking up stretch on new belts and of relacing and repairing old ones. Only one end of belt need be cut off in shortening; or to lengthen, insert stub of correct length.

Can be kept handy in stockroom or tool box for immediate service thus avoiding any possible delays. Represents big saving and convenience to your customers on any kind of belting. A complete service for all thicknesses of power or conveyor belting. A size and type for every need. Write on letter head for samples and trade prices.

FLEXCO-LOK

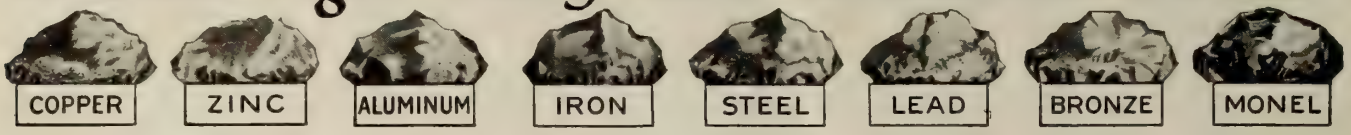
Steel Lamp Guards



Protects lamps from breakage and theft—property from fire. An efficient, inexpensive security against danger, losses and delays.

Made in all styles and sizes with reflectors and handles if desired. Patent lock prevents theft. Sold at a distinct economy to the purchaser. Write on letterhead for information, prices, etc. Not in stock in London.

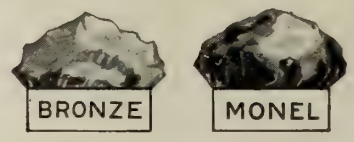
FLEXIBLE STEEL LACING CO.

4610 Lexington St., Chicago, U.S.A. *Stocked by the Best Supply Houses in Canada* 135 Finsbury Pavement, E.C. London

Of these eight widely used commercial metals-

Acids destroy

COPPER ZINC ALUMINUM



Rust corrodes

IRON STEEL

Heat weakens

LEAD

Steam wears & salt water pits BRONZE

Monel alone stands up against the many destructive forces that quickly break down the resistance of most commercial service metals. Because it is strong as steel, more corrosion resisting than copper, more wear-resisting than bronze, an increasing number of manufacturers are using MONEL metal for products for the most exacting and difficult industrial service, as well as for the most common domestic uses.

The name Monel identifies the natural nickel alloy — 67% nickel, 28% copper and 5% other metals—produced by The International Nickle Company.

THE INTERNATIONAL NICKLE COMPANY OF CANADA, LIMITED

Harbor Commission Building. Toronto, Ont.

THE INTERNATIONAL NICKEL COMPANY

Mechanical Details

Built as an enclosed unit with a series of pipe coils mounted above a powerful fan-wheel. Coils heated by exhaust or live steam. Cold air is drawn into the heater by the fan, impelled upward and around the coils, heated, and then diffused through outlet hoods to every part of the open area.

Where steam is not available, we supply our direct-fired type DF, which burns coal, coke or wood. Fan operated by any power available.

"At First, I Didn't Believe What I Heard About This Heater"

"But there it is—one single heater, with no outside pipes or ducts—keeping this whole place warm. It is the only system that has ever heated our plant *all over, all the time.*"

Investigate This Yourself

The amazing ability of Skinner Bros. (Baetz Patent) Heaters to thoroughly heat large factories, foundries and plant interiors is almost unbelievable. But we guarantee it—if a Skinner Heater ever fails it becomes immediately returnable to the factory at our expense and every dollar of your money will be refunded. The heater is portable—requires no special foundation—costs 15% to 50% less to install than any other system. Operating cost is equally low.

Find out more about this heater. If you wish, we will send you names of users so you can make an independent investigation.

"Modern's" Superiority Results From "Modern" Design

No other Self-Opening Die Head is like Modern. "Modern" is simple. There is little to get out of order—little to need adjustment. The output of a "Modern" is remarkably free from "spoils".

Chasers of a "Modern" cannot change position during work. Chasers have ample support for any duty within the capacity of the head in which they are used. Chasers will not "rock", "cock", or "bell at the mouth".

"Modern" Self-Opening Die Heads are fully guaranteed in every particular. Made in 17 sizes to thread 1/16 in. to 7 in. Each size will accommodate a wide range of diameters.

Let us send you a complete bulletin of these dependable die heads—faster, more accurate, last longer.

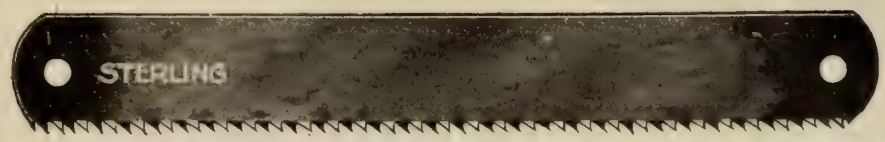
Speeding Progress in Photography

FEW would think to-day of going on a journey without a camera. Nearly every home owns one. Yet living men still remember the time when the travelling artist provided the only means of satisfying the very human desire for a picture.

The progress of photography presented many complicated mechanical problems. The die-casting process helped many manufacturers in the solution of these problems. Franklin Die-Castings are to-day used in cameras both commercial and scientific, helping manufacturers to reduce production costs and increase output.



In 1892 we originated the Die-Casting Process. For nearly thirty years we have been reducing the cost and simplifying the output in many fields of industry. The addition of the standard No. 12 Aluminum to the Tin, Lead and Zinc base alloys already in use has enabled us to meet a still wider range of individual needs.

We quote from samples or blueprints. Write for booklet, "Franklin Die-Castings in Many Fields."

"Good tools may not make a machinist—but the lack of them very often *un-makes* him. So I'm telling you, son, make sure that your Starrett Tool outfit is *complete.*

"Don't borrow. It will pay you to go down to the hardware store, and look over the Starrett line, and *buy.*

"You can't help feeling sore at these birds that are always borrowing. Every time you lend 'em something it peeves you and upsets you. And that shows in your work.

"Another thing, it often happens that the lender needs the tool loaned, while the other fellow is still using it. So the man who owns the tool has to wait around for the borrower to get through with it. And of course that looks bad.

"That's why men who borrow tools usually aren't popular; and as a rule when anybody is laid off, they 'get the gate'.

"Myself, I never lend my Starrett Tools to anybody. I think too much of them to pass them out to machinists old enough to have a set of their own. And you can't begin to get 'em too young.

"First thing to do—right *now*—is to write for the Starrett Catalog No. 22.

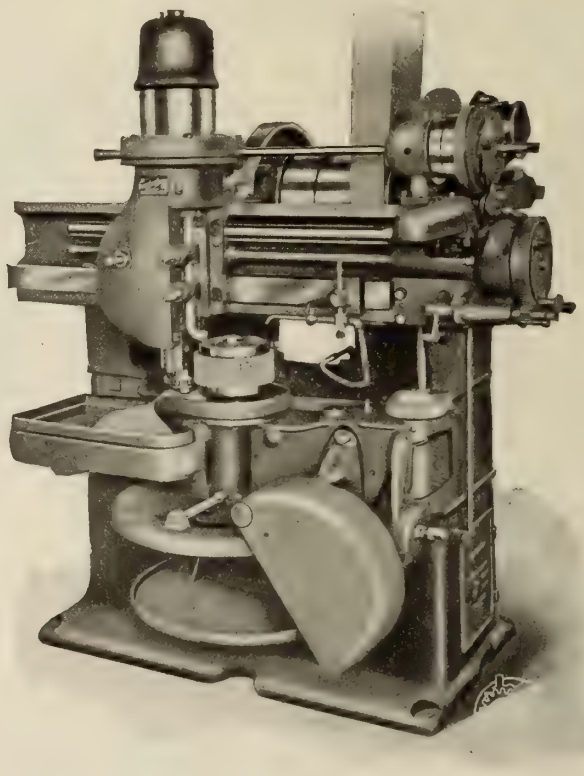
Gear Cutting With the "IFS" Left Out

The Gear Shaper Way



A production manufacturer knows that he will secure good gears IF he has an accurate cutter, an accurate machine and a machine working on the correct principle. The whole question of good gears is resolved in this little word "IF."

When the Gear Shaper was originally designed, the question of "IF" was taken into consideration and every possible means known to mechanical engineering was employed to eliminate the "IFS" from gear cutting.

That we have been successful in solving the problem is evidenced by the fact that each ensuing year sees a larger number of manufacturers adopting the Gear Shaper method.

How the Gear Shaper has accomplished this is clearly explained in our general catalog "Commerical Gear Cutting," which is a treatise on the subject of:—
Gear Cutting with the "IFS" Left Out.

Send for your copy to-day

"Why Don't You Use PHOTOSTAT Prints"

And the PHOTOSTAT makes no mistakes.

It makes photographic facsimiles.

Let us send you a booklet containing letters from many firms telling of large savings through the use of the PHOTOSTAT.

It is not necessary to carry around large, awkward blue prints for field and shop work. PHOTOSTAT copies can be made either of the blue print or of the original drawing, in a few minutes time, and at a convenient size so that they will fit into a loose leaf book which is easily handled. Furthermore these copies will not fade or smut and being of uniform size can be conveniently filed for future reference after the job is completed.

The installation of a PHOTOSTAT in an industrial plant means the elimination to a large extent of tracing work, because pencil sketches are copied direct in photographic facsimile; or, if the original sketch is not available the blue print can be copied equally well. Catalog pages, advertising layouts, maps, production charts, test reports, and documents of all kinds are also copied in photographic facsimile by the PHOTOSTAT with a great saving in time and money.

The PHOTOSTAT is made by the Eastman Kodak Co., exclusively for the

"The Tools You Buy Again"

COMPETITION of today demands that you use tools of QUALITY. For your drilling, reaming and milling cutter operations, put your faith in Butterfield Drills, Reamers and Milling Cutters. As compared with any ordinary tool they cut faster, more accurately, require less power, less re-grinding and give longer service—and they cost no more than ordinary tools.

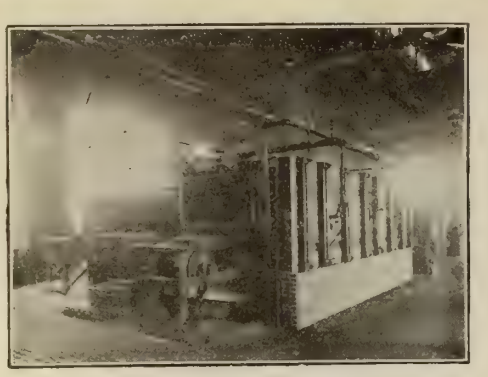
BUTTERFIELD

Nichrome the Casting Durable

Carbonizing Economy

involves more than cost of equipment. Results in the heat treated parts should get first consideration—if the reason for case-hardening is to be fully justified.



Furnace equipment that makes for uniformly good results at lowest cost not only keeps spoilage of expensive materials to the minimum, but includes long-life CONTAINERS.

The physical characteristics of Cast Nichrome Containers vary so little with repeated heating and cooling that heat penetrates readily and uniformly at all times during the entire guaranteed life of thousands of hours at 1,800° F. These, in brief, are the reasons for the extensive use of Cast Nichrome Containers in hundreds of plants where either economy or uniformly high grade results—or both—are the big consideration. Booklet N-21 gives more details.

Quantity Production of Shafts in Automatic Heat Treatment Furnace.

PRODUCTION MANAGERS

The following advantages are secured by the Continuous Method of Heat-Treatment :

Increased production per unit of floor space.
Reduction in manual labor per unit of production.
Uniformity of product, resulting in decreased scrap, following less dependence upon the human element.
The fuel economy that naturally follows the direct transfer of heat in spent gases to incoming material.
Improvement in working conditions by cooler shop.

In short, the saving in cost of the finished product due to economy in labor, time, fuel, floor space, decreased rejections, etc.

Do these advantages appeal to YOU?

Write nearest branch for Bulletin 217-T and learn whether this method is adaptable to your product and manufacturing conditions.

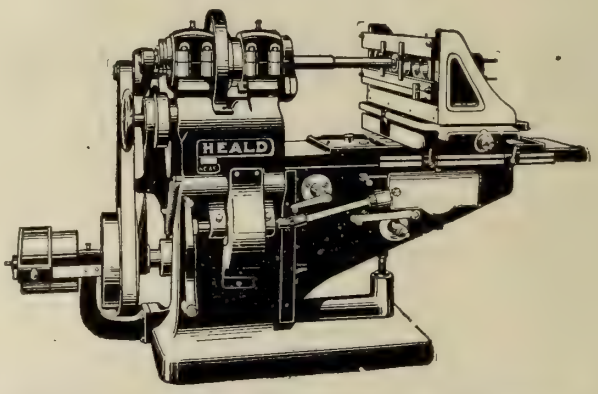
H.W. PETRIE LIMITED

CANADA'S DEPENDABLE MACHINERY AND SUPPLY HOUSE

H.W. PETRIE LIMITED TORONTO

The "PETRIE" policy represents the standard in high-grade tools and efficiency in service.

MACHINERY and SUPPLIES



REMEMBER the house of H. W. Petrie, Limited, when in need of anything in the shape of machinery and supplies. A colossal stock of machine tools of every description always on hand from which you are assured of getting the exact tool to suit your requirements. Included in this great array are many used tools. They are in good conditions and warranted to give satisfactory service. If you are seeking an opportunity to buy equipment at rock-bottom price don't fail to see our line of used machines.

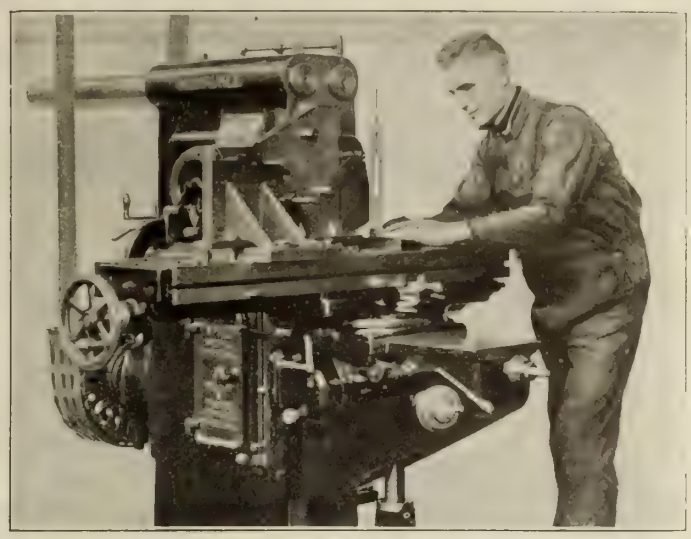
SERVICE.—A competent staff of engineers is at your service at all times; submit your problems to them; their advice costs you nothing and it is highly authoritative.

Another factor of importance to remember in dealing with the house of H. W. Petrie, Limited, is this: the quickest of service is always rendered on orders large or small.

Get the Cream of a Profitable Business

Regrinding Cylinders makes used motors better than New

Style No. 55 handles all sizes and shapes of cylinders



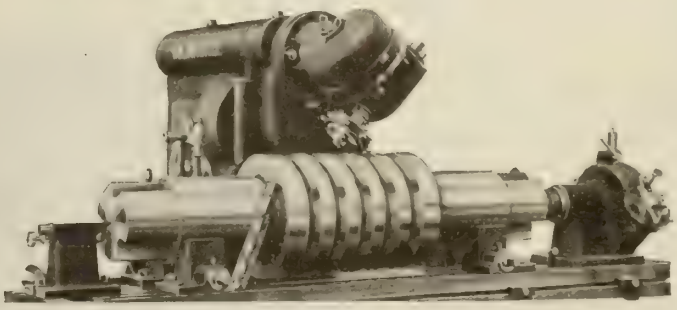
There is no business to-day that has the possibilities and which fits as nicely into a small machine shop, automobile repair shop or a concern doing welding, as the regrinding of worn or scored cylinders. Heald style No. 55 is built expressly for regrinding work. It is simple, moderately priced, self-contained, and has a very large capacity and range, easily taking care of singles, doubles, four and six en bloc cylinders.

Over Half a Century of Unequalled Success

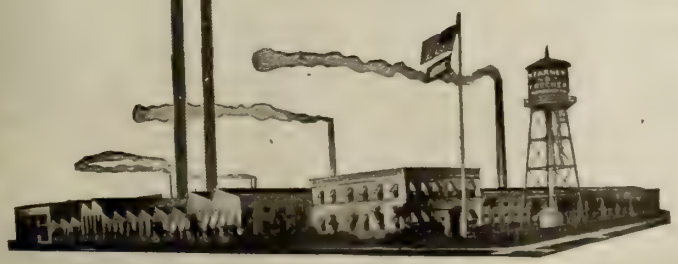
H. W. PETRIE, LIMITED

TORONTO - HAMILTON

MILWAUKEE MILLING MACHINES



Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

Oakite Cleans Aluminum at 1/20th Former Cost

A MANUFACTURER of engineering instruments uses Oakite materials for cleaning aluminum parts, and improves working conditions at a fraction of former cleaning cost.

The old method of removing polishing oil and emery consisted of hand brushing the parts with high grade gasoline that cost 40 cents a gallon.

Now clean without hand brushing, by washing in a solution made of Oakite materials, cost only 2 cents a gallon.

Fire risk is eliminated—work comes through in perfect shape — and the saving of 38 cents on every gallon of cleaning material reduces production costs.

Greater Economy In Drilling Small Parts

It's important to assure economy in drilling large parts.

But large wastes are likely to lurk in uneconomical methods of drilling small parts, too.

And opportunities for reducing costs may be overlooked if small parts are bought already drilled.

Hoefer drilling equipment enables you to economize in drilling small parts as well as large parts.

One type of Hoefer Driller, for example, drills and taps 1500 nuts an hour in six different combinations of size and shape

Another type of Hoefer Driller turns out 1440 piano caster wheels a day.

And we could go on indefinitely with similar cases.

Do *you* drill small parts or buy them already drilled? If you do, let Hoefer Automatic multiple drilling equipment help you reduce your costs on such items. We'll gladly advise you without obligation.

Send for the Hoefer Catalog.

VOL. XXVI. No. 1. July 7, 1921

Milling 7500 Drill Tangs Every Ten Hours

Vertical Milling Practice. Examples of Work Performed, Including Milling Drill Tangs—Monkey Wrenches—Various Shaped Levers—Bearing Caps—Plier Bearing Caps—Plier Bodies—Gear Pump Bodies and other parts.

By J. H. MOORE.

LIKE many other types of machine tools, the vertical miller has made rapid strides in efficient design during the past few years, until at present they have become a manufacturing tool with a very wide field of usefulness. Operations that were previously performed on other machines have been transferred to the vertical miller with splendid success, and in every way this type of miller has lived up to its name, "A Production Tool."

A feature that helped considerably to popularize this style of machine, was the continuous milling attachments that could be placed on top of the regular table. This feature can of course be adapted in some cases to the horizontal type of miller, but the vertical style lends itself very readily to the use of such attachments. This will be readily apparent when readers study the examples of continuous milling shown in the present article. Without entering into the design of such machines, we will proceed to discuss examples of work performed.

Contrary to an erroneous belief, continuous milling fixtures are not always expensive. True, in some cases, where the work is of a particularly intricate character, the cost of the fixture may be more than usual, but in the average case a tool designer will be able to produce a simple fixture that will serve the purpose. For example, the fixture shown at Fig. 1 could not be termed elaborate, yet it holds eight different

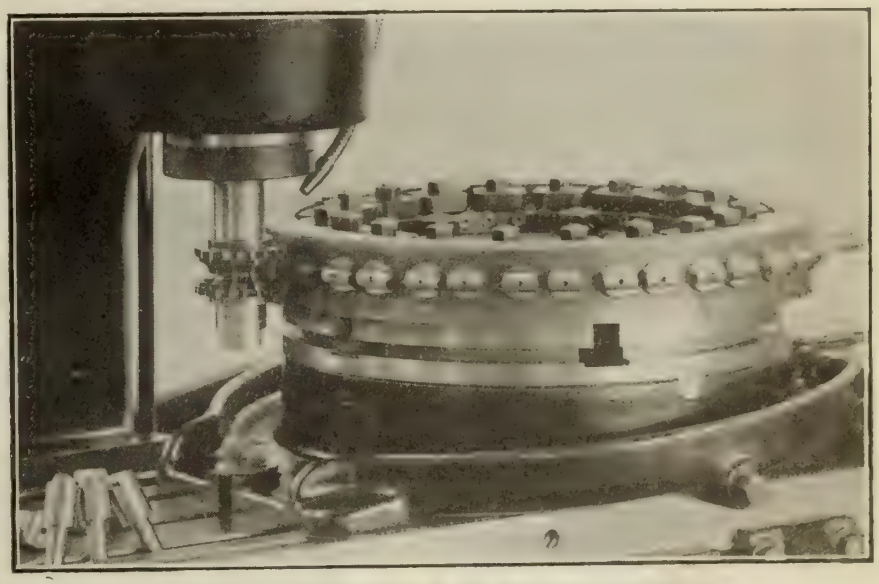

FIG. 5—MILLING RADIUS ON ROLLER PLUNGERS.

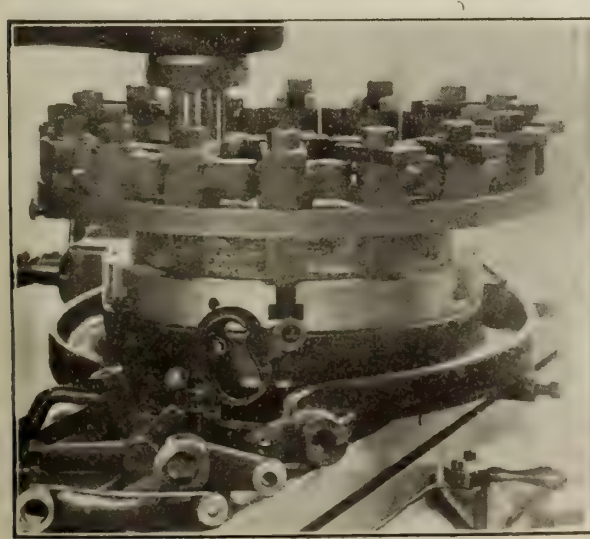

FIG. 1—SIMPLE LEVER MILLING FIXTURE.

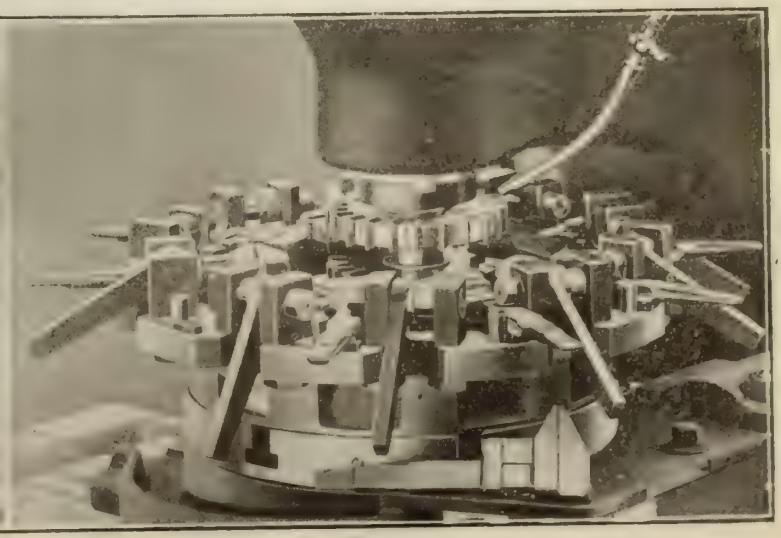

FIG. 2—MILLING MONKEY WRENCH BODIES

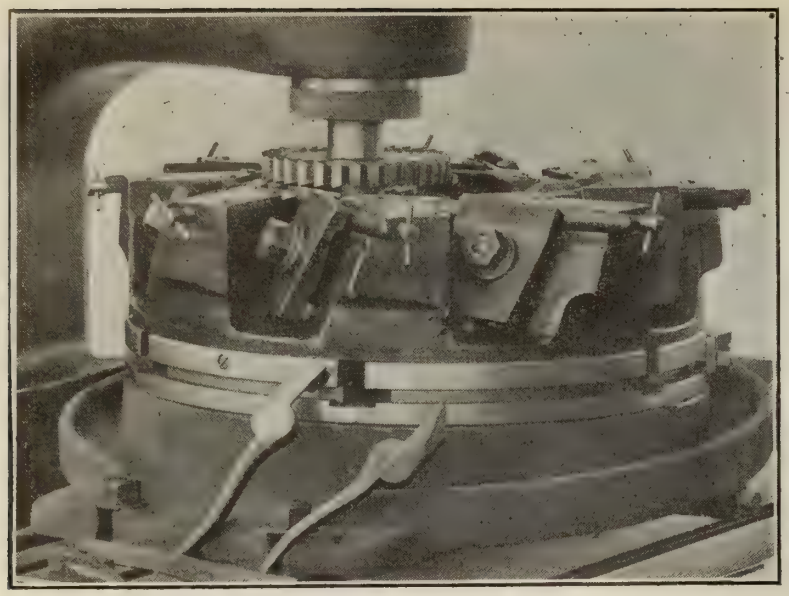

FIG. 6—MILLING THE SIDES OF PLIERS.

styles of levers, all of which are shown resting on the table of the machine. The fixture is of the adjustable type, the holding studs being removable. In the photograph, sixteen levers are being milled on their bosses.

The next illustration. Fig. 2, shows the milling of monkey wrenches at the rate of 3,000 every ten hours. The special fixture depicted is arranged with an eccentric, quick-changing device, this allowing fast removal of the parts, no cutting time being lost while changing. It will be noted that both these fixtures are mounted on the regular rotary table attachment as used on such machines.

Milling Drill Tangs.

Fig. 3 illustrates a very simple fixture, yet one that has saved considerable money for the firm that is using it for milling the tangs on their drills. The fixture is attached to the rotary table as shown, and the drill shanks placed in the double binding clamps, which can be clearly noted in the photograph. On drills having a No. 3 taper shank, 750 per hour were milled, this production being limited to the speed of the operator in changing the drills. There is also considerable saving of time in the setting up of these drills, as they formerly used to set the drills in a row so that six or more tangs could be milled at one time. As the cutters were at that time arranged on a horizontal spindle, it took quite a time to align up these cutters with the holding fixture to get the tangs central, and as the limit allowed was .001" plus or minus, each set of cutters had to be adjusted after each grinding.

This difficulty is overcome by the use of the continuous method, as only one set of cutters have to be aligned. Should the tang not be exactly central, this can be corrected by adjusting through the vertical feed. As stated previously, the drills are held in place by V blocks and clamps, each clamp holding two drills. To keep the tangs uniform in length, a ring gauge is used on the inside of the fixture, the cutter straddling this gauge, but not touching it.

Milling Bearing Caps.

Fig. 4 depicts a continuous milling operation being performed in the Le Roi Co. motor shops. In this case the machine is milling cast iron bearing caps at the rate of 100 per hour, and the cutter used is a 4½" high speed end mill. One man handles this production with ease.

The fixture used, as can be noted, is very simple, but before leaving this particular photograph, we shall, for the benefit of those readers not familiar with the method of driving such rotary tables, discuss the matter briefly. On looking at the photograph closely, it will be noted that a universal joint shaft connects the driving spindle of the rotary table to the feed box of the machine. This of course, allows you to vary the speed of the table at will, just as you would vary any other speed on the miller. The interior design of such tables does not interest us, so we will pass on to the next example, Fig. 5.

In this view we see a very interesting operation. viz., the milling of the radius on the roller plungers as used on the knee of Milwaukee milling machines. A high speed, formed concave cutter is used, and the holding fixture is arranged with clamping bolts as shown, each bolt binding two parts, as can be noted at the back portion of the fixture. The production time on this operation is 120 pieces per hour.

At a later operation, these parts, using the same attachment, are turned around ninety degrees in the fixture, when a slot is cut through the formed portion at the rate of 150 per hour.

The previous examples shown, also the present one, are all performed on

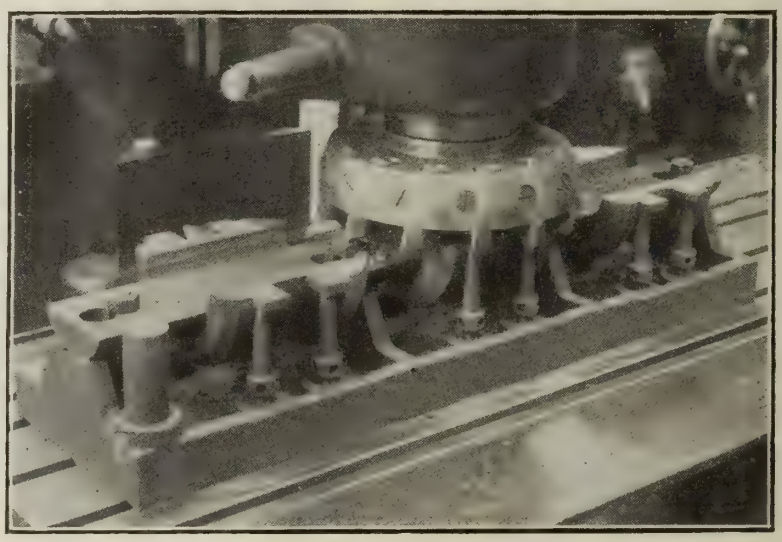

FIG. 7—MILLING HEADSTOCK CAST IRON BEARINGS.

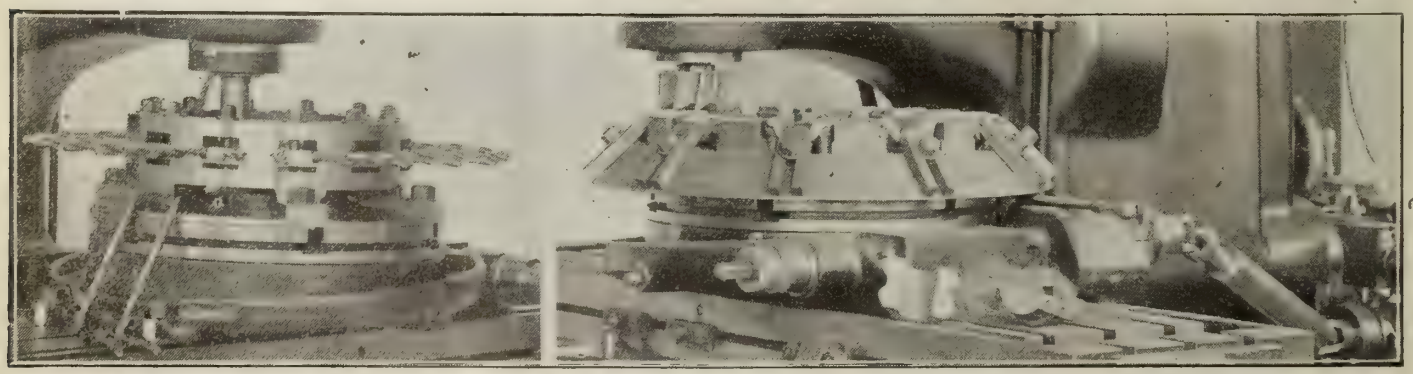

FIG. 3—MILLING TANGS ON DRILLS

FIG. 4—MILLING CAST IRON BEARING CAPS.

*Milwaukee milling machines, and in the case of Fig. 6 we see the method employed at the plant of the Mathias Klein Mfg. Co., Chicago, in milling the sides of pliers. The fixture shown is adjustable, it being possible to mill three different sizes of pliers in the same fixture. On the eight-inch pliers, shown in the photograph, 120 pieces per hour are produced. Formerly this operation was performed on a disc grinder, but due to the extreme toughness of the metal, the disc wheel would not stand up for more than 1,000 or so pliers. This was naturally too expensive, so milling was adopted, and the cutters at present complete over this amount without regrinding.

English Practice.

Next we shall consider a few typical examples performed on †Herbert machines, these being of English design. Fig. 7 depicts the milling of cast iron bearings for headstocks. These castings are later lined with babbitt, and the fixture shown takes three castings. It is adaptable for various sized bearings, the studs and clamping pieces being removable. In the operation shown, an inserted tooth cutter is used, the speed being 25 r.p.m.; the feed 5 3/16" per minute. The work is completed in one cut, the amount removed varies depending on the condition of the castings.

In the previous illustration, also the present one, it will be seen that the fixtures are mounted directly on the regular table, but as these two parts do not lend themselves to continuous milling, the reason for not using a rotary table is self-evident.

The operation at Fig. 8 shows the machining of the base and clamping down tongue on the sole plate of square turrets for capstan lathes. These pieces are drop forgings about 35 to 40 tons tensile strength, and in order to mill the dovetail portion and the base, three types of cutters are necessary, the cutters being changed without removing the work. A 3" inserted tooth face cutter is used for the base, with a feed of 5 3/16" per minute, while for the tenon, an end mill 2" diameter is used at the same feed. For milling the dovetail, an angular cutter is used at a feed of 3 7/16" per minute. Two parts, one partially completed, the other one finished, can be noticed resting on the machine table.

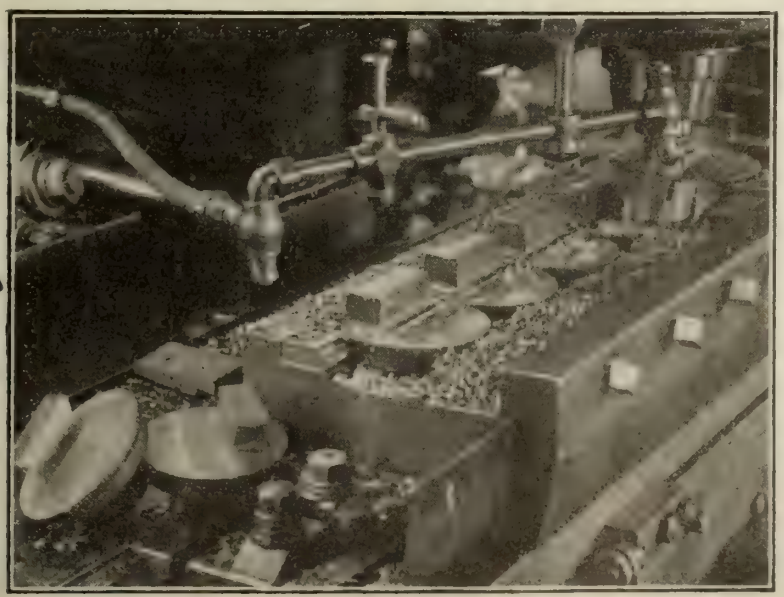

FIG. 8—MACHINING BASE AND CLAMPING DOWN TONGUES.

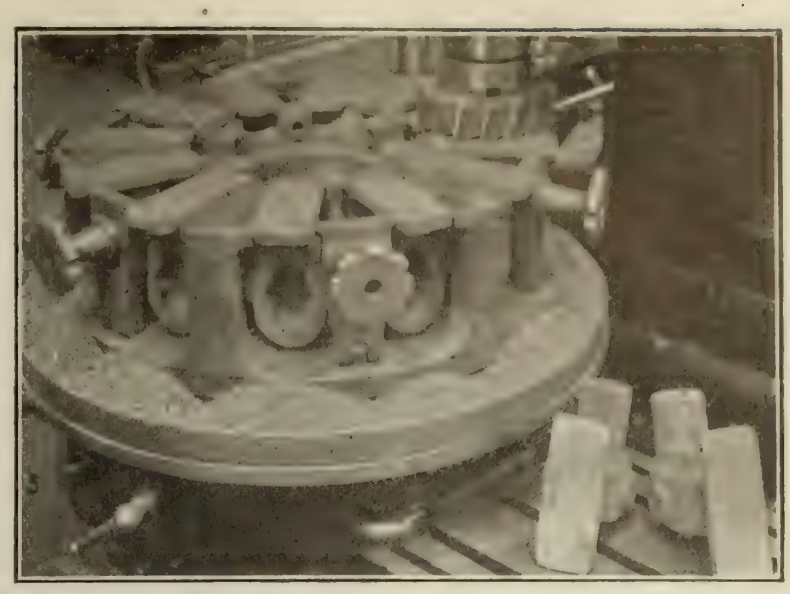

FIG. 9—MILLING BASES ON GEAR PUMP BODIES

Before proceeding to the remaining illustration, here are a few examples of work produced on these machines, but which we have not the space to illustrate.

In one case tee slots on cross slides were milled with a 2" x 5/8" tee slot cutter at a spindle speed of 93 r.p.m., and a feed of 2 3/4" per minute, from 250 to 300 castings being machined between grindings of the cutter.

Two other examples were the milling of stop rod brackets for turrent lathes, and a continuous milling operation on some pump covers. In the former operation, the parts are clamped directly to the table with ordinary clamps, and an inserted tooth cutter 4" diameter is used to mill the work. This cutter runs at 47 r.p.m., the feed per minute being 5 3/8". The latter operation used a 7" cutter running at 30 r.p.m., the output being 40 pieces per hour.

The last illustration, Fig. 9, shows a continuous milling operation, the work being the bases on gear pump bodies. The fixture, which holds ten castings, rotates under a 7" diameter cutter running at 30 r.p.m., and the work is completed at one cut. Of course no time is lost in machining, as loading and unloading takes place while the machine is in operation. The depth of cut varies from 1/16" to 3/32", the output being 40 pieces per hour.

To completely cover the field of usefulness of vertical millers in an article of this nature is impossible, for we can but scrape the surface of its possibilities. Such can be used for machining many types of small parts on various machines, such as sewing machines, typewriters, guns, etc., and in many instances you will find a complete line of vertical millers engaged in different operations on the production of machine tools, and small tool parts generally. The automotive industry has also found the vertical miller a valuable aid in the production of parts for automobiles, and in fact any phase of machine work has had a like experience. Of course this type of miller has its place, just the same as the horizontal type, and their work is independent one of the other, although in some cases work has been taken from a vertical miller to a horizontal type, and vice-versa. It is largely a matter of good judgment on the part of the plant engineer as to what style of machine tool best suits his purpose.

SELFLOCK NUTS.

The Selflock Nut & Bolt Co., Inc., East Syracuse, N. Y., have forwarded some interesting literature on their line of self-locking threads. They state that these threads areequal in strength to other threads and only differ in the shape of their cross sections. The base of the self-locking thread is deflected a few thousandths of an inch. Because of this difference in form, such threads have to be forced into engagement with standard threads, and the resulting friction has to be overcome when they are separated. This is the reason the makers claim they positively lock. These Selflock nuts are made for use on standard threaded screws. They may be used either side down, and if reversed when applied the second and following times, their locking efficiency will remain practically constant. These nuts are said to resist heavy and severe vibration tests, and are made in all grades and finish for every purpose.

Tools Used In Making of Precision Lathe

Interchangiability a Big Feature—Drilling Headstock—Milling Carriage Nut—Drilling Double Ball Cranks—Machining Lead Screw Bracket—Drilling Apron, and Other Operations.

By ROBERT MAWSON

THE making of a precison lathe is by no means an easy task. The very word "Precision" is a guide-post, and as the word implies, the elements that go to make up such a lathe must be made accurately. Interchange-ability is another essential feature, this in turn calling for special jigs, tools, and fixtures. We shall, in the matter to follow consider some of the special fixtures used.

It is highly necessary to show a photograph of the lathe itself, for practically every mechanic knows what a small precision lathe looks like.

The first operation on the tailstock, (on the particular lathe we are describing) is milling the base. The fixture used for this purpose is shown at Fig. 1. The casting is placed in the fixture and forced against the steel vee shaped locating blocks A; this being accomplished by the screws B. The base of the piece is forced into contact with stop C by means of screw D. It has been found that this method of locating and holding is very satisfactory. The fixture is held on the miller table in the usual manner, and a notched face cutter used for milling the faces.

The Headstock.

In drilling the head stock for a tee headed bolt a very simple fixture is used, and in boring out the headstock, the fixture shown at Fig. 2 is adopted. This boring operation is performed on a milling machine, and the piece is placed on the base of the fixture A, which it will be observed is made with similar ways to that used on the lathe for which the head stock is designed. The head is held on the fixture by means of a tee headed bolt which fits into the machined slot C. The two brackets D, also fit on the fixture ways, being held in position with tee headed bolts operated by means of handles, one of which is shown at E.

Bushings are provided in the brackets to guide the boring bar F, so that the hole will be machined parallel, and in correct alignment. It can easily be seen that all elements bored will be interchangeable as similar surfaces are employed to locate them, also the guide bushings are fixed as regards height from the milled face of the base. The hole is then bored out to 2 5/8 inches, leaving .002 of an inch for finish reaming.

The operations followed when machining the tail-stock are similar to those for the head-stock. The casting is first milled on its base using a suitable fixture to hold it. The spindle hole of tailstock is next bored, using the same fixture as shown at Fig. 2, but using different bushings to suit the bar ued.

The advantage of using the same fixture for boring both the head and tail stocks is that the locating surfaces being similar, also the guide bushing holes, the centers of both elements will be in the same height of plane from the lathe bed.

The nut to operate the carriage is made in two parts and the first operation when making this element is milling the base and later machining the joint surfaces. The two pieces are then placed in the jig shown at Fig. 3, the parts being held in the fixture by means of the four screws A, which are placed on a slight angle, and thus forcing the pieces down onto the machined base. The screw B is employed as the fixed locating pin, therefore the element at the left is tightened up first. The strap C is afterwards fastened by means of the nut shown and this assists in holding the sections in the jig.

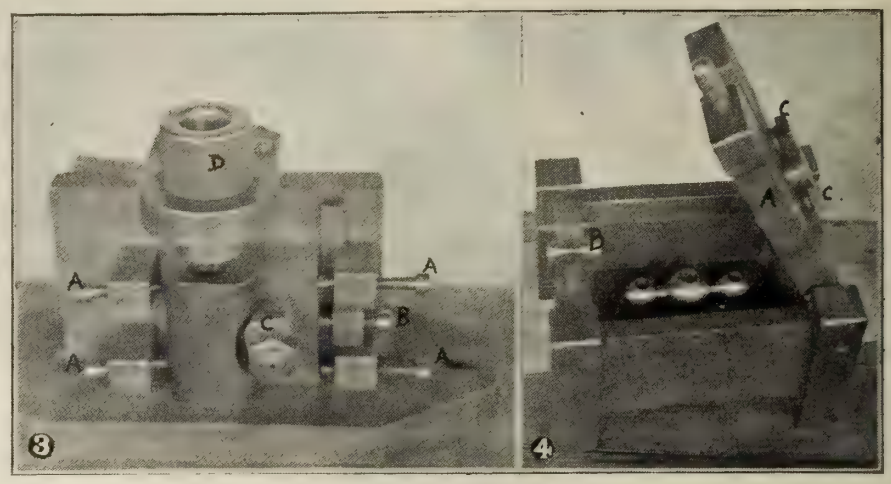

FIG. 3—JIG FOR DRILLING NUT.

FIG. 4—DRILLING DOUBLE BALL CRANKS.

The hole is first bored, the tool being guided in the long bushing D. This machined hole is then tapped with an Acme thread 5/8—8 threads to the inch, the split nut being 2 1/2 inches long. The tap is also guided in the bushing, so that the threads will be true and therefore move the carriage in a straight line.

Drilling Double Ball Cranks.

The illustration, Fig. 4, shows the jig used for drilling the double ball cranks. This piece is first turned to the proper shape and located in the jig by means of two cup bushings in which the two outer balls rest. The cover A is dropped down and fastened with the thumb screw B. The two screws C are next tightened, this action forcing the crank into the cup bushings holding it securely in position. Holes are drilled part way through the screws so that the drill will not come in contact with them during the machining operation.

A 5/16 inch hole is drilled, the drill being guided through the bushing in the cover. The jig is then reversed and two 1/4 inch holes drilled in the outer balls, the drill being guided in bushings placed in the base of the jig.

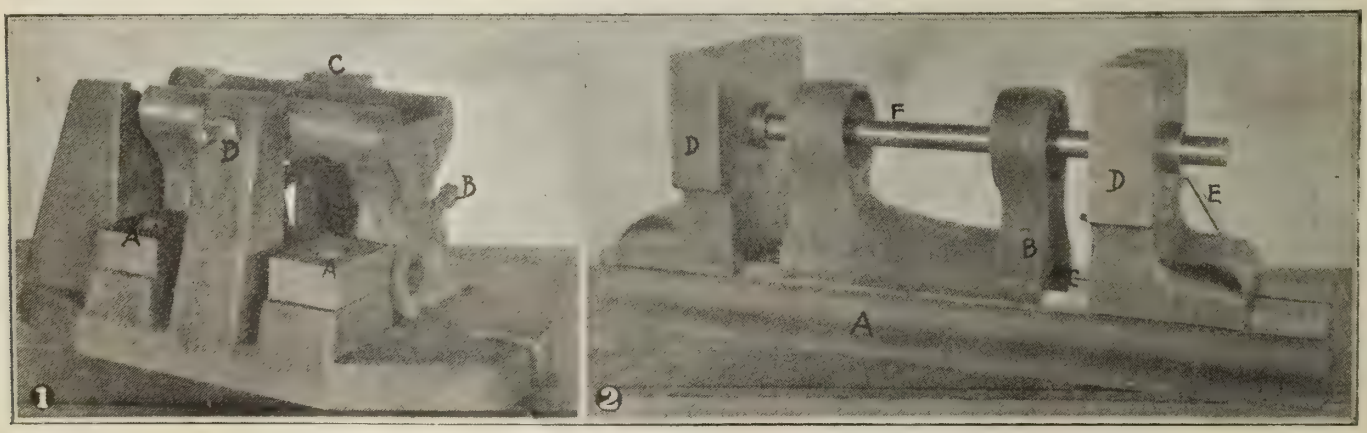

FIG. 1—FIXTURE FOR MILLING BASE.

FIG. 2—METHOD OF BORING HEADSTOCK.

The jig shown in Fig. 5 is used to machine the lead screw bracket. The casting has been previously milled on the joint face which is used to attach it to the lathe bed. The element is located by means of a stop at the left hand end. The screw A is then tightened, this forcing the casting back in the jig against a similar machined contour to that of the part. A 7/16 inch hole is now spot drilled and reamed in the piece, the tools being guided in the bushing B, and a ⅝ inch hole also spot drilled and reamed in the bracket through the bushing C.

It will be seen that this tool is of simple design, but it has the advantage of being almost fool proof as the man can see clearly if the piece is correctly located before commencing the operation. The drilling of the steady rest base follows the operation of milling the bearing surface that rests on the lathe bed, and the fixture employed for the drilling is shown in Fig. 6.

The casting is located by means of the machined base which is placed on a similar finished surface as shown and held in position by means of the bolt B, which fits in a hole which has been previously drilled. Two screws C are next tightened against the bosses of the element. The sliding member of the jig is next revolved on the pin D until the edge of the fixture comes in contact with the stop screw E.

A ½ inch hole is now drilled and reamed in the boss F, which is in a vertical plane. The block and screw E is then removed from the jig and placed into another location, which is hidden in the view shown. The sliding part of the jig is now swung against this new location. This brings the boss G into a vertical position when a similar hole is drilled to that made in the other boss. It will be noticed that this fixture is not provided with guide bushings, the men placing the holes in the centre of each respective boss.

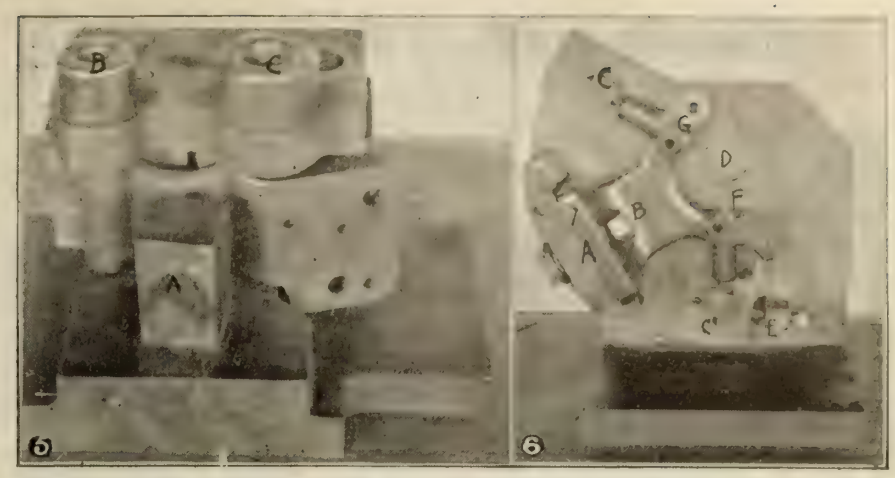

FIG. 5—JIG FOR LEAD SCREW BRACKET. FIG. 6—DRILLING STEADY REST.

Drilling the Apron.

The illustration, Fig. 9, shows the jig used when machining the lathe apron. This casting has been previously milled on its face to the proper outline and is located in the jig by means of the hardened steel block A, which fits accurately a milled recess in the piece. The cover is then dropped down and held with a thumb screw. Two screws are next fastened down on the element to hold it securely. The following holes are then drilled in the casting, each being guided through bushings to obtain the correct alignment:—Two 21/64" holes; one 9/16" spot drill and ream; one ½" spot drill and ream; one 25/32" drill; one 7/16" spot drill and ream, and one 1 9/16" bore, using a bar which is guided in the largest bushing shown. The latter hole s afterwards threaded with a tap 1⅝ inch 16 threads; this tool being also guided in the same bushing to obtain a well directed thread.

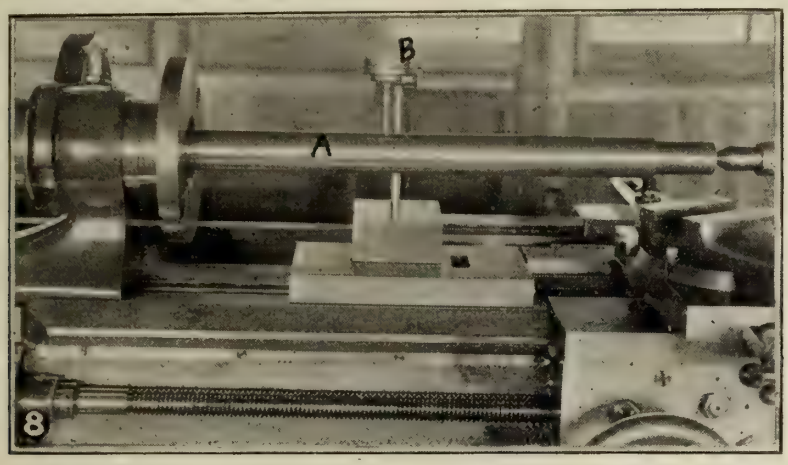

FIG. 8—SHOWING THE ALIGNMENT TEST.

Testing Alignment.

After the lathe has been finally assembled the head and tail stocks are tested to determine if they are in alignment. The method followed for making this test is shown in Fig. 8. The ground arbor A, which is made with the correct taper to fit the head stock, is placed as shown, fitting the head stock, and resting on a center in the tail stock. The arbor is revolved. The inspector moves along the dial indicator B, when he can read on the gauge if the arbor oscillates, which would of course prove that the heads were out of alignment.

Further, the error, if such is in evidence, can be ascertained at the two ends of the arbor, and if this be greater than called for on the specifications, the fault is rectified until the lathe meets the requirements. The advantage of this type of testing device is that the conditions are similar to those employed when the lathe is in operation for turning; fitting in the collet hole of the head stock, and revolving on the ordinary center at the tail stock end.

Other testing gauges used on the lathe are shown in Fig. 9. The block A is the tool used for testing one size

Management Problems of the Small Factory

Comprehensive Plan of Procedure Essential—Factory Planning Should Originate in the Office of the President—The Factory Should Not Prepare the Master Schedule

*By ERNEST CORDEAL

THE difference between success and failure in business, and particularly in manufacturing, is frequently found in the presence or absence of a comprehensive plan of procedure. No one would think of starting to build a house until all of the details of its design had been settled upon and working prints prepared to guide the mason and the carpenter; no one would start upon a hunting trip without figuring in advance what provisions and ammunition would be required; yet only too frequently is a factory operated day after day and year after year with no more plan than is employed by a band of children at their play.

The importance of a plan may be illustrated by an actual example, disguised but not exaggerated, of a condition existing in one factory and fairly representative of the situation in many plants where no thought has been given to panning production. The product of the plant under discussion consisted of but one type of machine built in twelve sizes. A very few of the parts were common to all sizes, a few more were used on two or more sizes, but the majority while identical in design, were of different dimensions for each of the twelve sizes. The yearly and monthly requirements to fill sales orders were very regular and could be predicted months ahead with only a small percentage of error. Practically no finished stock of machines was carried, orders being filled direct from the shop.

Responding to a well executed advertising camaign the demand for the product of this factory was largely increased. The manager, who was a competent executive and salesman but knew nothing of factory practice, called upon the shop for a greatly increased output, at the same time giving the superintendent permission to increase his force to whatever extent he should deem necessary. More men were hired, double shifts were put on all the machines, wholesale orders for rough materials were placed and the foundry was placed on a twenty-four hour basis. The shop soon assumed the appearance of intense activity, every wheel was turning, material crowded the runways, the accountant complained that the inventories were showing enormous increases. But weeks passed and production had not been increased by a single machine.

After two months of more than double expenses, with nothing to show in the way of increased production and orders being cancelled by the score because of delays in delivery, the explanation of the factory failure was discovered. In the store room were found seven hundred finished parts, representing thousands of dollars in labor and overhead, for one type of machine, the demand for which averaged less than two a month. For the most popular size, which constituted more than thirty per cent. of the total sales, three thousand parts of one kind were found but of another part, a drop forging which was furnished by a distant factory, there was not a single one on hand, less than one hundred on order and six weeks required to secure delivery.

With finished parts in the store room sufficient in value to complete more than three months' production it was scarcely possible to furnish to the assembly floor enough material to keep it going a single day. The foundry had been taking off two heats a day for weeks and yet certain castings were entirely out of stock. Every machine had been working to capacity building up great stocks of parts which were not required or could not be used until other parts were finished. In some cases material had not been ordered for parts for which the final assembly department was waiting.

THINGS TO AVOID.

There is nothing which disorganizes a factory so badly, which causes a greater falling off in efficiency or which more surely contributes to losses than a shortage of certain parts or certain materials required in the completion of the product. When the purchasing department fails to keep the factory fully supplied with rough materials, an endless succession of expensive difficulties is started.

There is nothing to be gained by insisting that losses should not occur and by ignoring the possibility in planning the factory work. In planning, account should be taken of all losses which ordinarily occur in parts production and proper allowance made in issuing orders.

Incidentally it might be mentioned that a simple planning system introduced in this factory more than doubled production in less than two months with an actual reduction in the working force.

Where Planning Should Start.

Factory planning should originate in the office of the president in the form of a master schedule prepared several months in advance. This schedule should take into consideration first, factory capacity for the production of the various lines, types and sizes and second, estimates of the sales department as to the probable demand for the several articles.

The practice is sometimes followed of permitting the sales manager to prepare the master schedule, but this ordinarily is an error. The sales department is naturally interested in securing a large production of those articles which are most easily sold. The average sales manager is inclined to measure the efficiency of his department in gross rather than in net income and for that reason sometimes strives for volume without sufficient study of the relative profit realized on the various lines. Again the sales department rarely possesses, nor can it be expected to possess, a comprehensive knowledge of shop operating conditions.

Efficiency in the factory demands that the volume of production of the various lines be kept within certain limits so that machines and departments may be employed to the best advantage and kept as nearly as possible in a state of balance. The sales department, in its desire to increase gross receipts, is all too likely to ignore the effect which an unbalanced production program will have on factory costs.

The Factory and the Master Schedule.

It would be an equally serious mistake to permit the factory to prepare the master schedule. In this case it might be expected that the superintendent would outline a plan which permitted the greatest efficiency in factory operation without regard to the possibility of disposing of the product. Fortunately in most manufacturing organizations there is an official who is above and not directly connected with either the selling or the factory departments and he is the person who is in the proper position to tell the sales department what they shall plan to dispose of and the shop what they shall prepare to produce.

With the information which every executive should have at hand there should be no great difficulty in preparing months, or preferably a full year in advance, a schedule of production divided into weekly or monthly periods. In making such a schedule the wise executive will call in his sales manager and his superintendent and take advantage of their detail knowledge of conditions as well as secure their best cooperation in the carrying out of the plan by making them parties to its preparation. The minor executive who has expressed his opinion as to the feasibility of producing certain results will make a far greater effort to attain them than he will to follow out a program about which he has not been consulted. Such is human nature.

With a master plan before him the sales manager may proceed to outline his advertising and selling compaigns. He will, of course, endeavor to better the estimate of sales which the master schedule contains but in doing so he will, as nearly as possible, direct the energies of his force toward selling the items upon which the factory can make the greatest profit and toward keeping the sales closely in balance with the capacity of the factory for the various classes of product.

The factory superintendent, as soon as he has been provided with a copy of the master schedule, can proceed to line up the work of his entire shop. If the product is a complicated one requiring a large number of parts and sub-assemblies he will find it expedient to prepare shop and foundry schedules in complete detail. If, however, the product is one of comparatively simple units, containing few parts and requiring no long and complicated operations, a very simple schedule covering the daily or weekly output of the various departments may prove sufficient.

Ask for Bids Early and Avoid Delays.

If a separate purchasing department

* From *Industrial Management.*

is maintained it also will find it necessary to go over carefully the master schedule and to ask for bids on the material which will be required and place orders in ample time to avoid any possibility of delays to the factory. Not the least merit of the planning system is that, if properly followed out, it permits the utmost economy in the purchasing and carrying of materials. When no plan is prepared in advance the task of the purchasing agent is indeed a difficult one. He must either order materials in sufficient quantities to protect all possible requirements, in which case he is very likely to be criticized because of heavy inventories of rough material, or he must take chances of seriously delaying the work of the factory, and when that happens he is sure to find himself in trouble.

The actual procedure followed in planning will depend entirely upon the facilities which the factory offers in the way of records and reports unless it is considered worth while, as it will usually be, to introduce whatever additional system is necessary to complete production control. In a plant where a complete system of production orders and a perpetual inventory is in use planning in the shop is simply a matter of making use of the information at hand as to parts in stock and in process as a guide in the issue of orders to the several departments. With the master schedule as a basis a weekly or monthly chart may be prepared showing the number of parts or sub-assemblies of each kind required to complete the production for the period. The number of parts required less the number on hand and in process leaves the balance for which orders must be placed in the parts production departments. All production orders under a planning scheme are dated as to require time of completion.

Best Procedure for Small Factory.

Ordinarily in the small factory it should not be necessary to carry the planning beyond the point of giving to each department a detailed list of the work to be completed during a given period, preferably not exceeding a week. Where production orders are issued to all departments from a central office the placing of the dates required on the orders serves the purpose of a schedule for the several foremen. The effective plan will, of course, make proper allowance for the completion of parts and sub-assemblies in advance of the time when final assembly operations are scheduled to start.

Where a foundry is operated in connection with the factory the schedule for that department will obviously have to be dated several weeks ahead of the machine shop and perhaps a month or more ahead of the assembly floor. The purchasing schedule will also have to be made well in advance of the production schedule and in times when material is difficult to get or when deliveries are uncertain it may be advisable to put out purchase orders several months in advance of required dates. There is nothing which disorganizes a factory so badly, which causes a greater falling off in efficiency or which more surely contributes to losses than a shortage of certain parts or certain materials required in the completion of the product. When the purchasing department fails to keep the factory fully supplied with rough materials an endless succession of expensive difficulties is started.

Introducing a Planning System.

The factory which has not perfected its production order system will find it advantageous to do so when introducing a planning system. It may be feasible in some factories to operate effectively without the production order, depending upon a department schedule and the assignment of work by the foreman, but ordinarily the use of the production order to cover every job which goes into the shop is the only effective method of directing factory work. The production order system should, however, be as simple as it can be made.

FACTORY PLANNING.

Factory planning should originate in the office of the president in the form of a master schedule prepared several months in advance. This schedule should take into consideration first, factory capacity for the production of the various lines, types and sizes, and second, estimates of the sales department as to the probable demand for the several articles.

The actual procedure followed in planning will depend entirely upon the facilities which the factory offers in the way of records and report unless it is considered worth while, as it will usually be, to introduce whatever additional system is necessary to complete production control.

There is no necessity, except in the very largest plants, for an elaborate assortment of forms to be used for the different classes of work, nor is it necessary that the production order carry a mass of information which is a matter of common shop knowledge. In the very large plants it may be often advisable for production orders to carry complete instructions as to the operations to be performed and as to the tools and jigs to be used, but in the shops of moderate size where the work is largely a repetition day after day of the same operations there is no possible advantage to be gained by employing additional clerical help to put information which is perfectly well known to foremen and workmen alike on production orders.

Schedule of Output Affects Production.

The value of the schedule of expected output in guiding the preparation of production orders will be readily understood. When a central office, either that of the superintendent or a special production department, issues all the orders for the factory general supervision is greatly simplified and control of production is rendered more easily effective. The entire factory is of course, run for the benefit of the final assembly department and with the production system under central control the balancing of the work of all departments so as to bring together at the proper time and in the proper number all of the parts required for the completion of the scheduled product is made easily possible.

The perpetual inventory, if complete and accurate, is of the greatest assistance in conducting a planning system. If the material records show correctly and at all times just what quantities of parts are on hand in a finished state, in process and in the rough the process of planning parts production is made very easy. With such records it is only necessary to compare schedule requirements with stocks on hand and to prepare orders on the shop or foundry or on the purchasing agent for the additional materials either rough or finished which will be required.

It must be admitted with regret, however, that very few perpetual inventory systems function with sufficient accuracy to make them of any use in connection with planning. If the perpetual inventory is not absolutely dependable it should not be permitted to endanger the proper working of the planning scheme but rather should be disregarded in the preparation of schedules. If the perpetual inventory is not available then it is necessary at each period when a new schedule is worked out for coming months to make a complete check of stock to ascertain whether or not the necessary quantities of rough material are on hand, what number of finished parts are available and what quantities are in process.

Planning and scheduling production would be extremely simple if only it were possible to eliminate all uncertain factors from factory operation. As this is not possible, even under the best conditions, allowances must be made for irregularities which are of constant occurrence and certain factors of safety must be established and observed. In building a bridge or a steam boiler no engineer would attempt to follow a design which called for materials of only sufficient strength to withstand the computed stresses and strains.

Not All Losses Can be Eliminated.

It is undoubtedly true, theoretically, that all losses in the factory, through defective materials, poor workmanship, machine breakdowns and innumerable other causes should be susceptible to elimination, but even in the best managed plants this ideal is far from realization. There is nothing to be gained by insisting that losses should not occur and by ignoring the possibility in planning the factory work. Every foundry turns out some bad castings, the best mechanic occasionally spoils a job and there are various other causes why parts started through the shop do not reach the assembly floor in proper condition to be used or do not arrive there at all. In planning, account should be taken of all losses which ordinarily occur in parts production and proper allowance made in issuing orders. Many a good planning system has fallen into disrepute because no consideration was given to possible losses.

It is not at all uncommon, even in fairly well managed factories, for losses of as high as twenty-five or thirty per cent. to occur in the finishing of parts, particularly those made from castings. Few managers, except those who have a complete follow up system and use it, realize how high the percentage of loss in manufacturing operations is. Accurate records of losses should be kept as the first step in their minimization and incidentally to assist in keeping the parts production schedule in balance. Some factories observe the practice of filling out all orders to the full number at the final operation by running additional parts for those spoiled at any point in process. This is a good system when practical but in the small shop where every machine must perform various operations on a number of parts it is rarely possible to make up losses which occur after the first or second operation. The best system in such factories is to compute for each part the usual percentage of loss and to start each order with a sufficient

additional number over those required to make up the difference.

A factory turning out a product for which they also furnish repair parts has an additional problem in planning. It is not usually possible, except in the largest plants, to assign the furnishing of repair parts to a separate department but it is possible and should be made a practice to keep repair part orders separate from orders covering regular production. It is a very easy matter to determine from sales department records, provided the product has been on the market several years, about what quantity of each part will be required for repairs and orders can be placed in the shop at intervals to take care of such needs.

The actual procedure in the preparation of the production plan is a simple mathematical process. The master schedule obviously becomes the plan to which the final assembly department is expected to work. This schedule calls for the completion of a certain number of units of each kind during a given period. The superintendent in making his schedule for the shop starts at the assembly floor and works backward to the foundry or the rough material department.

Get the Assembly Schedule Uniform.

A practice which seems to be so common as to be almost universal is that of permitting the assembly floor to drag during the first part of the week or month and to crowd the greater proportion of the production into the last few days before the end of the accounting period. Such a method of operation should be discouraged by all means as it is obviously inefficient and as the hurry at the end of the period is unavoidably connected with a deterioration in the quality of the product. If an assembly schedule, assigning to each day its proper share of the production for the period, is prepared and adhered to it will be found that efficiency is automatically increased and quality of output bettered.

Theoretically a parts production schedule would be merely a list of all the parts required multiplied by the total number of units of finished product called for by the master schedule. In practice there must be some variation from this procedure. It is not always economical to run parts in so small numbers as would be needed to complete production for a single week or month. In the manufacture of parts on automatic or semi-automatic machines the time required to set up the job is frequently equal to that required to complete hundreds or even thousands of parts after everything is ready. In such cases it is obviously good practice to run several months, or years, supply of parts at one time provided, of course, that heavy carrying charges would not offset the saving in production cost and further that there is no danger of the design of the part being changed. Again the difference in the time required to complete the operations on the various parts makes it necessary to start parts of some kinds through the shop days or even weeks before other parts which go in the same assemblies need be scheduled.

The scheduling of work in detail, as is the practice in well managed large factories, is a desirable refinement of planning which may be employed to advantage in many factories of smaller size where the product consists of a complicated assembly, but in the average factory it is hardly necessary to go beyond the department schedule. The mistake should never be made of introducing any more system into a factory than is necessary to secure the desired results. Every form which a workman or foreman is required to make out should have its definite use, and that use should be thoroughly understood.

In the small factory the planning of the shop work can usually be handled by the superintendent himself or by a special assistant and it will be found that the duties and worries of supervising the shop will be minimized by the employment of a comprehensive schedule to cover the work expected from all departments. The ordinary factory fails of a high degree of efficiency mainly because of a lack of coordination between individuals and departments It matters little how diligently and intelligently each member of the factory force performs his particular task so long as the collective effort of all is not gathered as an effective whole into the completion of a product of good quality and economical cost. By means of planning the efforts of every member of the organization, from the sales manager and the superintendent to the man at the machine and the bench, may be made to contribute with full force to the desired result, more product and greater sales at less cost.

PROTECTING ALUMINUM

To protect aluminium and aluminium alloys from corrosion, L. von Grotthus has tried browning the metal electrolytically. The aluminium is suspended in an electrolyte consisting of a sulphur compound of molybdenum with a zinc anode at a temperature of 60° to 65° C. The aluminium is soon covered with a dark-brown coating, and may be bent or rolled without cracking the coating. Aluminium thus treated was immersed in a salt solution for two months without showing the slightest trace of corrosion.

DUST EXPLOSIONS.

Writing on the subject of dust explosions, in the Engineering News Record, Mr. David J. Price suggests that, in order to prevent high pressures from being built up within heavy concrete wall construction, consideration might be given to the use of a thin wall offering little resistance to the great volume of gases produced by the ignition of the dust. In such a building all the working stresses would be placed upon the concrete columns and beams, the walls serving only as a filler or curtain. Large window area, or the daylight type of building construction, affords another means of preventing high interior pressures. Recent explosions in two different lines of industry were localized as a result of this type of construction. Windows of the steel sash type, self-supporting and extending from the ceiling to the floor, would be preferable. Steel curtain doors have been used on the working floors of grain elevators. They can be opened during the day, providing good ventilation to the working floor and a vent for any explosion on that floor.

CIRCLE

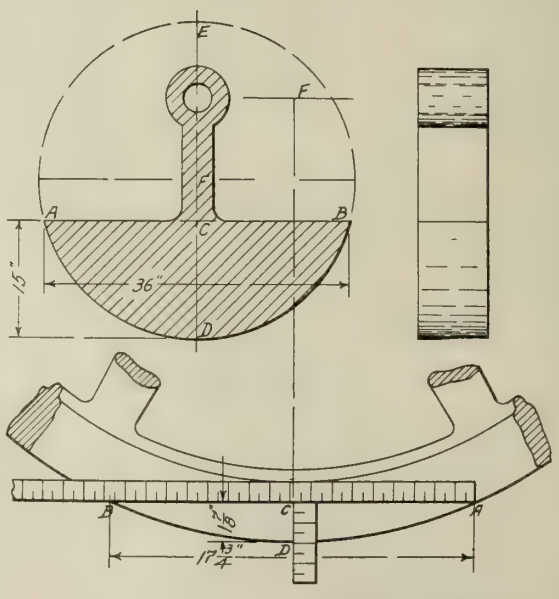
Finding Diameter from Broken Section

It is often required to find the radius or the diameter of a circle from a broken section, or where only a portion of the circumference is available. It is a rule of proportion that the height of a sector is to half the chord as half the chord is to the diameter of the circle, minus the height of the chord.

Using the cut here shown this would be, in formula form:—

C D : C B = C B : C E

Case 1———15″ : 18″ = 18″ : C E



$$C\,E = \frac{18'' \times 18''}{15''} = 21.6 \text{ inches.}$$

Diameter = C E + C D = 21.6 +15 = 36.6 inches.

Radius F D = 36.6 ÷ 2 = 18.3 inches.

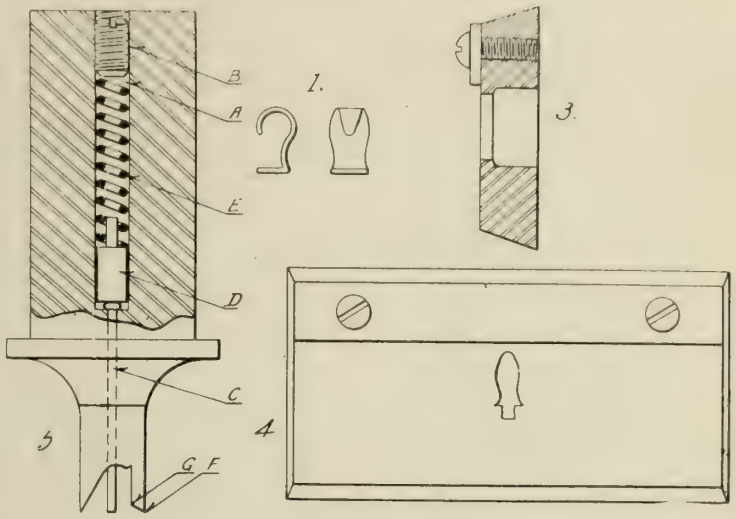
Case 2———1.875″ : 8.875″ = 8.875″ : C E

$$C\,E = \frac{8.875'' \times 8.875''}{1.875''} = 42.01 \text{ inches}$$

Canadian Machinery

WHAT OUR READERS THINK AND DO

PUNCH AND FORM DIE.



By C. E. H.

A very simple and efficient punching and forming die for making small metal parts at one operation, may be of interest to the readers of "Canadian Machinery," as the principles involved may be applied to various other shapes, and if a roll feed is used on the press the output is enormous.

The form shown in Fig. 1 is a cheap form of brooch catch and the number used of various sizes runs into tens of thousands, so that an economical means of production is an absolute necessity.

The die is of the shape shown at Fig. 2, and is made with 1" clearance out of about ½" material. The back of the die is cleared away to within about 3/32" from the face, Fig. 3. This is to insure each piece going clear through the die, as if one remained, the next would crowd on top of it instead of forming. This also facilitates the filling of the die, as very little metal is left for the die-walls.

The punch was made of 1¼" round annealed stock of the shape shown at Fig. 4. A ¼" hole was bored about 2" deep down the center of the shank (A), and tapped for about 1" down for a 5/16 grub screw (B). A smaller hole, as large as the formed portion of the punch will allow, is drilled from the other end to meet the large hole. This is for a stripper pin of drill rod (C) with a small head peened over to keep it from falling out. On top of this head is a small block (D) about ⅜" long, made to slide loosely in the larger hole, and a spiral spring of music wire (E) is placed behind it and the tension regulated by the grub screw (B).

SHOWNG HOW THE PUNCH AND DIE WAS MADE.

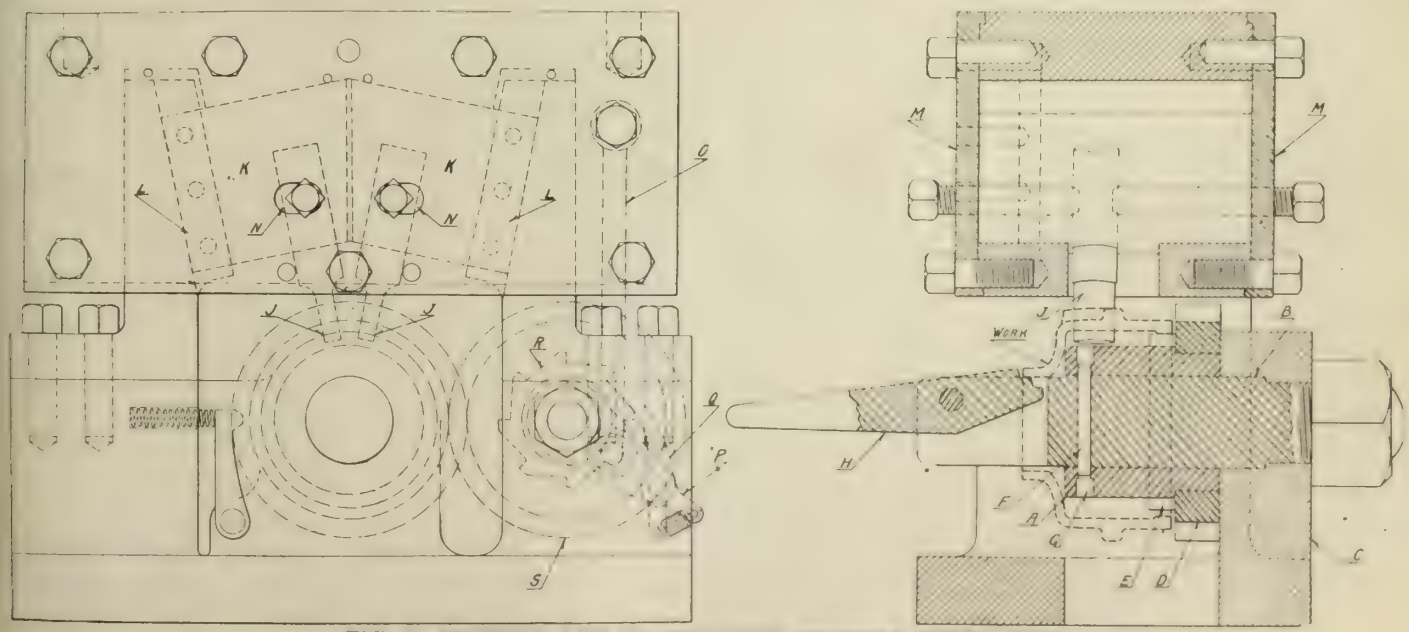
As the punch descends, the two outer edges begin to cut the metal and the inclined portion curls the piece being cut into the desired loop. The other leg cuts from F to G and then bends the work to a right angle, forming the base of the catch, and when the punch fully enters the die the whole is cut from the plate, and the stripper pin which has been depressed is released and pushes the catch clear of the die and so leaves room for the next to curl properly.

Several sizes of this type of die have been in operation in one shop for a number of years and have given constant satisfaction.

AUTOMATIC DEVICES NOT ALWAYS PROFITABLE.

(By L. George.)

In these days of mass production on repetition work the tool designer is frequently requested to make the fixture as near automatic as possible, so as to eliminate as much of the human element in its manipulation as it is advisable to do so. When this policy is carried to the extreme it is not surprising to see cases where time and money has been expended on tools and fixtures that are unnecessarily complicated. Some fundamental condition may have been ig-



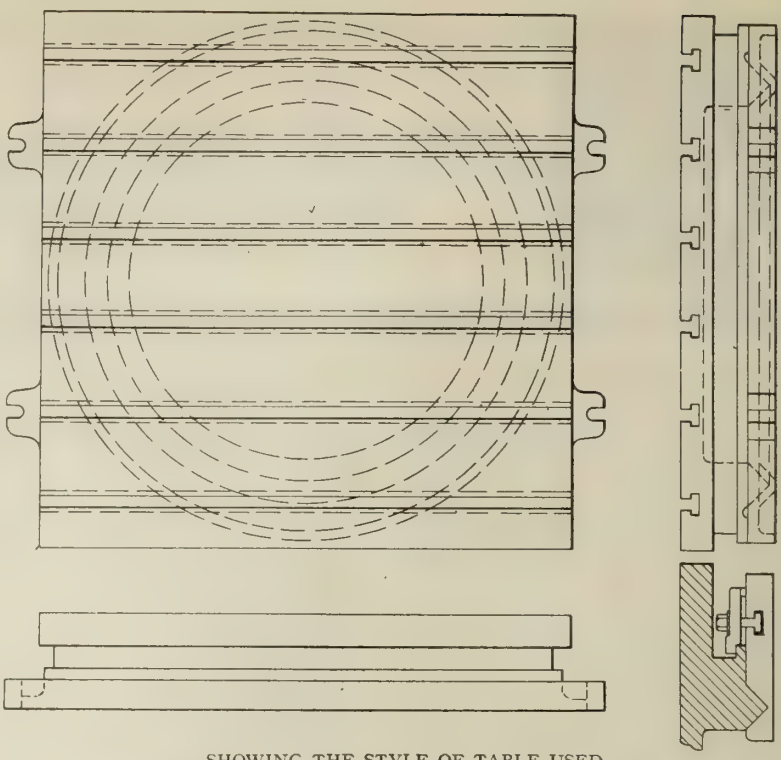


FIG. 1—SHOWING THE COMPLICATED FIXTURE FIRST USED.

nored and the designer overshoots the mark with too intricate an idea.

The accompanying article describes an instance in point. The operation was the broaching of spoke holes in a malleable iron hub. The piece, shown in Fig. 1., is slipped over the sleeve A, which can revolve on the center pin B secured in the bolster C. The sleeve carries a gear wheel D, the teeth of which is a multiple of the spoke holes, and which has projections E to engage with those of the hub. A pin F retains the sleeve in position by engaging with the internal groove G. A lever H in the slot of the horizontal pin keeps the hub in place and helps in its release.

Two radial holes are to be broached at each stroke. The punches J are held in separate blocks K, the latter being retained by means of dovetails in the inclined ways L of the bolster, so that the movement of the punches is radial to the axis of the hub. Cover plates M attached to the upper bolster have slotted holes N to permit of horizontal movement to the screws securing the punches. At the rear a rod O, attached to the upper portion, gives motion to an oscillating arm or lever P and pawl Q, which at each up stroke turns the ratchet wheel R and gear S, thereby rotating the sleeves and the work through twice the angular pitch of the spoke holes. A blunt catch engaging with the gear teeth holds the work ready for the down stroke. As can be seen from the sketch, the device was designed for the punching of two holes at the one stroke of the press, but owing to the pitch of the different holes varying to an uncertain degree, the fixture did not prove satisfactory, resulting in many broken punches and other difficulties.

The complicated fixture was subsequently discarded and replaced by one similar to that shown in Fig. 2. This does not represent the identical fixture but illustrates the idea which proves successful. Here the hub is placed on the pin ,rotated by hand, one hole being broached at a time. The machine may be run continuously and broaching and unloading is performed quicker than in the previous fixture, and the cost of the latter device was only a fraction of that of the first mentioned.

SHOWING THE STYLE OF TABLE USED

AUXILIARY TABLE.

(By John Homewood).

A very useful auxiliary table to be used on a planer for light work that would be difficult to reset when cutting a surface square with the first cut. The revolving part can be elaborated by graduating the cylindrical surface so that angular cuts can be taken. The drawing does not show in detail the stud that retains the parts together. In conjunction with an angle plate this revolving table can be used to great advantage in shops doing a general line of work where variety is predominant.

MAKING PRECISION LATHE

Continued from page 69.

of collet B, and the male gauge C is used for testing the hole in the head stock, both holes in the block being interchangeable. If the collet and gauge fit both, also the lathe, the desired conditions have been met. The ring gauge D is used for testing the collet E and is made a perfect counterpart of this element. The gauge F is for testing the hole in the headstock machined to suit the collet in question.

The concentricity of the machined hole in the headstock is also tested as a separate unit and the tool employed is shown at G. This is made with a ground surface that fits accurately the collet hole in the head, and after it has been placed into position the inspector tests by means of a dial indicator resting on the protruding end H, if the head stock revolves without oscillation, or in other words, if the hole is concentric.

Other gauges and testing methods are employed on the various elements but those described will show the reader the care exercised to not only obtain, but ensure an accurate precision lathe.

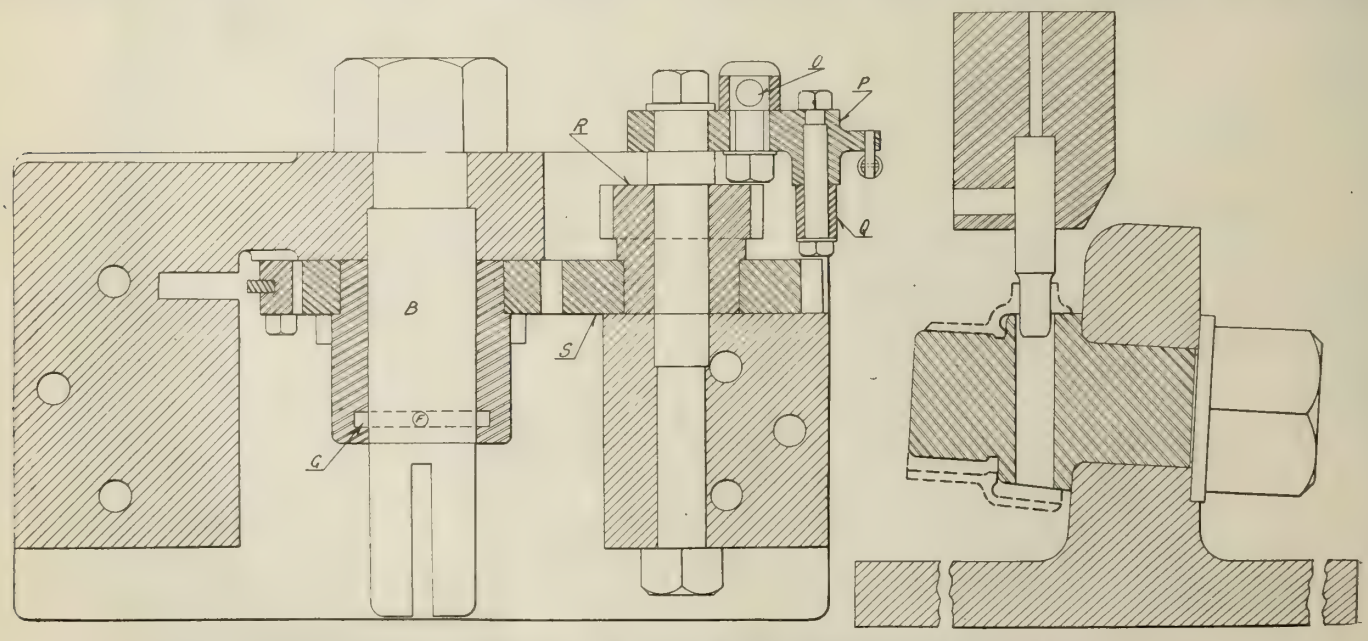

FIG. 2—A SIMPLE TYPE OF FIXTURE WHICH IS MUCH BETTER THAN THAT SHOWN AT FIG. 1.

The Brinell Testing Machine.—Some of Its Uses

By CHIEF CHEMIST ALFRED HERBERT CO., COVENTRY, ENGLAND.

THE Brinell method for testing the hardness of metals was introduced in 1900, and is now accepted by many as the most accurate and reliable hardness test for all classes of steels, and for most of the non-ferrous alloys. Apart from its laboratory uses, it is essentially a workshop machine and there are very few progressive firms dealing with the heat-treatment or extensive machining of metals which have not one of these instruments installed in the works. It is simple to work and when used with a knowledge of its capabilities it can control the heat-treatment of steels in particular more efficiently and more rapidly and economically to my mind than the older method of tensile testing.

The particular machine with which we are dealing has several distinct advantages. It is purely automatic and practically foolproof, giving absolute accuracy without requiring any exertion in applying the pressure. Being operated on the weight system, it has no oil leakages or gauge defects to guard against and attention has been paid to details which affect the output of the machine.

It is an established fact that the Brinell hardness numbers follow very closely the tensile strength of the same types of steel, whether the steel be heat-treated or otherwise. It is therefore particularly applicable to the rapid testing of parts for which it would be impracticable to take regular tensile tests, such as the majority of forgings and stampings, heavy shafts, etc. Where large quantities of steels are used in repitition work; charts may be made for each steel showing its various properties, so that the Brinell test after heat-treatment gives all the information required. This applies particularly to alloy steel which are generally heat-treated to give either hardness as the first essential or the maximum combined strength and toughness. In the first case, after quenching in oil from 800° to 850° C., the article is tempered at 200° C. This should give a Brinell number of over 400, and the steel is not machineable. The value of such a machine is evident, for, although 400 or over will be satisfactory for gears and parts subject to wear, 375 will be decidedly too soft.

In the second case, tempering is usually between 550° and 650° C., depending to some extent on the size and thickness of the parts. The qualities desired for shafts and parts subject to shock and torsional stresses are obtained when the Brinell is about 250 to 270, and in this state the steel is comparatively easy to machine. When the hardness number reaches 285, machining becomes difficult, and while the metal may still be cut at 300-320 Brinell, at a slow speed, this should never be necessary. A chart is usually built up from the properties of a bar 1-in. diameter, so that bars 8-in. or 10-in. diameter will not give quite the same results, particularly towards the centre. In a case of this kind, if the properties shown at 255 Brinell are required, it may be necessary to use a lower tempering heat which would give possibly 285 in the 1-in. bar. If much of this work has to be done, however, it is a simple matter to plot the tempering heat against the size of the bar, to give the approximate Brinell number required.

A Wise Plan.

Very often stampings are received by the user, which have to be machined at the first operation. In certain cases it is advisable to Brinell these to remove not only those that are too hard to machine, but also to detect any great difference in composition, and so prevent machining parts which would ultimately be scrap. When the stampings are to be heat-treated before machining there is no necessity to do this, but it is very important to test them after heat-treatment, and so ensure a uniform product passing into the machine shop.

The installation of such a machine has many indirect uses. Very soon each class of steel is given certain limits. When trouble is experienced it leads to the furnace temperature being more accurately recorded, or the composition of the steel is more closely specified. Any well-designed furnace, when properly used, will give a uniform heat, and this is easily indicated or recorded.

The carbon content of a steel when carefully made and allowing for slight segregation, need never vary more than .04 per cent. from the figure aimed at. The other important elements such as nickel, chromium, vanadium and manganese, which do not segregate to any extent, should come within quite narrow limits.

Once the steel is consistent and heat-treated within the correct temperature limits, the Brinell test is the only one necessary, and to my mind the only satisfactory hardness test for commercial work. The results are soon shown in the machine shop where maximum speeds can be used without danger of sudden stoppages, due to tool failures, and the number of complaints, valid and otherwise, as to difficulty of machining are very much reduced.

Necessity of Heat Treatment.

It is not only alloy steel which should be heat-treated. All carbon steel with over 0.25 to 0.30 per cent. carbon, are greatly improved after hardening and tempering, and in this condition can very often replace the more expensive alloy steels for parts not required with exceptionally high properties, and where the untreated carbon steel does not give a sufficient margin of safety.

It might be thought that for very soft steels used for casehardening, the Brinell test is of no value. This is by no means true, although a machine of this type is of no use for testing the hardened case, due to the core yielding under pressure, the "small ball" machine being more suitable. On the other hand it is very often most useful in detecting a steel not suitable for a certain machining operation. It may be taken that the softer the steel the more liable it is to rip and tear on machining, and that broaching is a worse operation for ripping, than milling, and milling worse than turning, especially if the cut be taken with the grain. So much depends upon the particular machine shop practice, the speed of machining and the condition of the tool, that figures can only be given with hesitation, but as a rule a steel will tear on broaching when the Brinell number is less than 120, and on milling about 100, or under. The elements on which ripping chiefly depends in very soft steels are carbon, manganese and phosphorus.

Phosphorus is intentionally kept in steel up to about 0.12 per cent. where the carbon and manganese are low, which has to be screwed or machined at a high speed, and where the parts are not subject to any great shock or strain. It has the same effect in cutting as a small amount of lead in brass or bronze. For steels for general casehardening work, the carbon and manganese are the most important elements, and, if only for machining, these should not be less than .14 per cent. and 0.60 per cent. and 0.80 per cent. A steel with the minimum figures specified by the Air Board S .14, with carbon 0.12 per cent. and manganese 0.50 per cent., especially if it has been normalized (heated to 850°/900° C., and allowed to cool in the air) or if the rolling has been finished at much over 800° C., will almost certainly give trouble in machining.

This applies more strongly to specifications for softer casehardening steels such as Air Board S. 13, where the carbon may be as low as 0.08 per cent. The Brinell machine, to my mind, is the only mechanical test of any assistance with these very soft steels, and if much trouble is experienced it can very often be overcome by its use alone. Where ripping is met with in higher carbon steels, it is usually caused by over annealing, either directly, or by piling at the rolling mills, and can generally be removed by suitable heat-treatment.

Casehardening Steels.

In the case of fractures of casehardened steel or parts broken say in straightening after hardening, a Brinell test on the core will always differentiate between a steel suitable for casehardening and a steel which is not. The Brinell number of the core of water-hardened bars 1-in. diameter and of the following carbon content is as follows:

Carbon per cent	Brinell No.
.10	107
.15	170
.20	228
.25	285

It will be observed that if the hardness of the core (when the part is 1-in. or more in thickness) exceeds about 250 Brinell, the steel may be looked upon with suspicion.

For non-ferrous alloys, the Brinell test is equally useful. Copper alloys harden severely when mechanically worked either hot or cold. In certain cases this hardness is removed by cooling from the forging temperature, but annealing is nearly always necessary. For example 60/40 brass stampings are usually annealed to give not over 80/90 Brinell, and in the annealed state the test gives an idea of the composition, as it varies inversely with the proportion of copper. So also in rolling 70/30 brass. This after cold rolling may be as hard at 160/170 Brinell, yet with

The Influence War Had On Lathe Practice

Little Lasting Impression Has Been Made on Machine Tool Practice—Revolutionary Advance Occurred in Gauging, Inspection and Interchangeability. Continuous Production Ultimate Goal

By RALPH E. FLANDERS *

WITHIN the memory of the author, the design of machine tools has been deeply affected by a number of influences. The first of these was the bicycle craze of the nineties. An important result was the development of the hand screw machine in the direction of heavier drive and feeds and stiffer structure to meet the demand of work like hub forming. Another line of improvement lay in the design of highly specialized machinery for the making of a single part. Such machinery had been almost unknown up to that time, as the bicycle gave the first opportunity since Civil war days for continuous production on work of moderate size. Machines of this new type were applied to spoke and nipple making, hub drilling, chain-link manufacture, sprocket and gear cutting, etc.

The second great influence was the invention and development of high-speed steel by Mr. Taylor and his associates. The effect of this invention began to be strongly felt in the first five years of this century, and was the chief factor in a continuous policy of redesigning for cutting power and rigidity which has been going on until the present time.

Cutter Versus Machine.

Meantime the high-speed tools themselves have been improved, while the ability to treat them and, still more, the courage to use them to the limit, have been steadily developing. As a consequence there has been a contest between the machine and the high-speed cutting tool much like the classic rivalry between the projectile and the armor plate. As soon as a machine was designed to use high-speed tools to the limit, better tools were provided and speeds and feeds were demanded which were beyond the capacity of any known machine.

The last important influence was that of the automobile. This statement is made advisedly, as the war, so far-reaching in its effect on human life and history, made really little lasting impression on machine tool practice. A few special processes were fostered, such as thread milling and form grinding. A really revolutionary advance was made in gauging, inspection, and interchangeability in general. This was induced by the necessity for assembling together parts made in widely scattered factories. But the effect on machine tools themselves and their actual operation now appears to have been negligible.

If we study the influence of the automobile on machine-shop practice, we can see why this is so. The industry, long before the war, developed to the point where parts were made in such quantities that most of the operations could be made continuous, one machine or many being set up and tooled for a single operation on a single piece, remaining on this operation hour after hour, day after day, and month after month. In spite of the immense amount of machine shop work involved in the activities of the war, only a minor percentage attained to this standard condition of automobile manufacture. For the most part it was ammunition and small arms only that were made in continuous production.

Continuity of Production.

Now this condition of continuous production is the ultimate goal of manufacturing development. It demands and employs every last possibility in cutting qualities of steel, power and accuracy in machines; and particularly in skill in the design of fixtures, tool outfits, and methods of machining. The fact that this goal was reached so early in American automobile manufacturing explains why the war did not stimulate new developments in machine tool practice. but rather acted as a retarding factor on the whole.

The influences just described have affected all varieties of machine tools, but this paper is limited to a discussion of the lathe practice as affected by the automobile. By lathe practice is meant not only engine lathes, but turret lathes, automatic lathes, automatic screw machines, and other machines in which cutting tools act on rotating work.

For the moment, at least, machines of the best design are more than adequate to the demands of the best high-speed steel now available. Development has therefore taken entirely new directions, and this is a most favorable moment to examine carefully its progress.

Present progress in lathe practice is in two radically different and, to some extent at least, opposed directions. The one relates to the expanding of the machine by giving it a number of spindles with a corresponding number of tool positions. This is best seen in the multiple-spindle automatic screw machine, now used almost exclusively for standard bolts, screws and studs, and for other parts made in large quantities. It is more costly than the single-spindle automatic, but not much more complicated, the cost arising principally from the extreme accuracy necessary in the indexing and spacing of the spindles. The difficulty of obtaining this accuracy is the limiting feature of the machine, but its scope is constantly increasing.

As applied to larger machines for chuck work on castings, forgings, etc., the machine becomes more elaborate, approaching the conditions of a number of separate machines united on one base. This results in considerable complication and cost, but spectacular producing capacity in many cases. There is the further advantage that the tooling—being spread broadly over the different positions—is simple, open and easily adjusted to suit individual needs.

The second line of progress is in the direction of providing machines having a large surplus of driving and feeding power and of rigidity. The limitation on output and accuracy now becomes an entirely new one. Instead of asking, "What will the machine stand?" or "What will the tool stand?" we ask "What will the work stand without springing, breaking, chattering, or tearing from the chuck?" The engineering problem thus becomes one of operation sequence, support for the work, tool design, and—in some cases—design of the work itself. This second development may be described as the intensive, single-spindle method.

*The author, who is manager of Jones & Lamson Machine Co., Springfield, Vt., presented this matter before the recent meeting of the American Society of Mechanical Engineers at Chicago.

BRINELL MACHINE

Continued from page 75

suitable annealing this will drop to 40/50.

Copper again is a most ductile material and when fully annealed has a Brinell of 40-45. For machining or screwing long lengths this softness is sometimes a disadvantage, so that the metal is slightly hardened by the addition of a small amount of arsenic, silicon, zinc, etc. In the case of copper for electrical work, this is not possible, on account of the great reduction in conductivity, so that the metal is not fully annealed, but partly annealed to give say 90 or 100 Brinell. In this state it has the required rigidity without materially affecting its other useful properties. A Brinell machine is absolutely necessary for this kind of work, and there are many instances where it gives valuable information to the user, who, as a rule, quickly adapts it to his own requirements and if necessary makes his own hardness limits for the particular class of material in which he is interested.

It is only necessary to add that the output of a testing mahine is much greater if a small grinder is at hand to remove scale instead of using a file, and when suitable holders are made for parts of irregular section. The impression should be made where the strain set up does not weaken or damage the article. As a rule, the width of the impression should not be greater than the distance from its edge to the edge of the part under test, and it should be made where it is least visible on the finished product.

NEW PAMPHLETS.

The Brown & Sharpe Mfg. Co., Providence, R. I., have issued various instruction pamphlets, these covering the method of reading the micrometer caliper, both in English and Metric measure, also the methods of adjustment and care of these tools.

Another pamphlet describes the method of reading English measure verniers with 20 or 25 graduations. Either of these pamphlets are obtainable at no cost.

WOULD LIKE CATALOGUES.

Messrs. Menary & Wetherell have opened up a machine shop at Wetaskiwin, Alta. They have purchased the business of the Wetaskiwin Welding Works, and both partners have had a varied experience in American machine shops. They state that they would like to receive catalogues or offers of lathes, etc., from Canadian firms.

Paint as a Profit Getter

PAINT is one of the things that can add greatly, not only to the permanence of the building, but to its better operation. The illuminating engineer, the plant oculist, the painter, and the power-plant engineer all work toward the same end. A little white paint works wonders in extending the lighting area of every light source, and in throwing the light everywhere, including corners otherwise difficult to reach.

A machine placed in a dark corner of the room, near the end wall, and yet where the row of windows in the side wall ceases, was difficult to operate in safety and with good production. A lamp which hung near the machine toward the central aisle did not do a great deal of good. But when the side walls near the machine were painted white, the machine suddenly lost its distinction as the darkest in the room.

White paint, throwing light upon the darker machines, continues "Factory," means faster work by the operatives, less discontent at being assigned to unfavorable machines and better health of the operatives.

Light should be not only fairly bright, but should be equally distributed. Sometimes equal distribution is interfered with by the line of belts or cumbersome machines. In one factory room the design provides for excellent lighting from the windows, both in the side wall and the end wall, but a section of apparatus run by overhead motors and belts obstructs the light from the windows in the side wall. As men constantly have to come and go to these machines, a dark spot behind this apparatus was illuminated with the result that the work progressed better.

Sawtooth windows give the best illumination in many cases. But here again a little white paint helps spread the light more evenly. Painting white the surface of all posts and the ceiling, still further diffuses the light so that all parts of machines are evenly lighted.

Improving Old Buildings.

It is not generally realized that paint may be applied effectively to galvanized iron as well as other kinds of pipes. Heating pipes have their life prolonged by being painted, and the white paint also gives an appreciable extra percentage of diffusion of light as compared with the gray galvanized iron surface. Heating boilers and other boilers should also be painted white.

This practice is becoming quite general now, whereas several years ago nobody would have considered applying white paint to a black boiler or low-temperature furnace.

Large machines are also painted in many modern shops. In some cases white paint is used. In one shop a light tone of gray is applied to most of the machines, and certain depressions such as the central webs of pulleys are painted a dark red, which gives a pleasing contrast with the light gray. The difference in the illumination of the room is at once evident after even one or two of the neighboring machines have been so painted.

The most economic means of increasing the effectiveness of the central part of the room in an old building is by careful painting so that the center of the room shall be as well lighted as the other parts.

The aisle which runs down the center of the average factory department has any things along it which should be well lighted. The aisle itself is the line of traffic; collisions, or even scraping of trucks against one another as they pass should be avoided.

Tunnels for piping between buildings should be painted white, unless they are of fairly smooth concrete. This keeps pipe tunnels clean so that a repair man finds it easier to locate any and also makes it easier to work there. The pipes in the tunnel should also be painted, excepting, of course, the ones that are covered with asbestos. These colors should correspond to any color code that may be used throughout the factory to distinguish water, steam, drinking and sprinkler lines.

Concrete, iron, and wood may all have the same paint applied to them, for the mill-white paint now has been scientifically determined so as to be effective on all these surfaces.

White paint reflects the greatest percentage of light striking at any angles and from all sources.

It Pays to Keep Posted

TO preclude purchase difficulties and to keep myself in touch with the greatest number of developments in trade laws, transportation rulings and laws and conditions affecting purchases in this city and in others in which we are likely to have dealings," says L. Herzog in a recent issue of System, "I have my secretary keep a scrap book of news items which bear upon these subjects.

All the newspapers and journals, including foreign publications which are likely to contain information which should be brought to my attention, come directly to this office. After a few months' training I find it possible to leave the selections of the valuable news items entirely to my secretary She clips the items, puts them in the scrap book and indexes them under headings, such as "Loading," "Tariff," "Lighterage Rates."

In addition to these news reports, we include in the scrap book all reports, concerning market conditions and rate exchanges received from our agents in this city and in other parts of the world where the basic deals affecting our business are made.

There may be months at a time when no one uses this scrap book, but whenever there is the slightest doubt about any condition surrounding a purchase, reference to this scrap book has usually been found a help in clearing up the difficulty. Its value at just such times as this is sufficient to justify a great deal more expense than is required to keep the book up to date.

Bushing a Loose Pulley

MANY of us have had and are having trouble with the loose pulley. We neglect to oil it because it needs so much attention. It usually means that we must find a ladder and do some climbing and risk our fingers. This is all wasted effort it seems.

The other day, while visiting a garage, continues W. T. Elzinga in American Machinist, I saw a dry grinder with a tight and loose pulley on the spindle, driven direct from the lineshaft. It was rattling merrily at the rate of some 1,500 r.p.m. and without attention, except perhaps once a week or even less. The pulley was worn at least 1/32 in. large and would soon need a bushing. The dealer selling this grinder said that the price being low no provision for a good oiling system could be made.

Having received permission to make an improvement we took the spindle to our school shop, bored the pulley about 5/16 in. larger and turned a cast-iron bushing to a sliding fit for both pulley and spindle. We next drilled about a dozen ¼-in. holes in it, so spaced that they were not in line with the oil hole in the hub, filed several helical oil grooves between the holes, filled the holes with plugs of felt (we keep an assortment of old hats for such purposes), tapped the oil hole in the hub for an oilcup, assembled the spindle and put it to work again. It has been running now for several weeks and the owner is happy because its noise does not distract him any more and he can forget about oiling it.

We have in our school shop a dozen or so pulleys with bushings from 1¼ to 3 in. in diameter so treated and they are certainly a great improvement over the old style. We have eliminated several counters on account of this kink. It seems that this bushing slips around in the hub and turns about half the speed of the pulley, distributing the wear over pulley, bushing and spindle.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Readers no doubt missed the contest in June 30th issue, but the omission was unavoidable. Following are those with correct lists for June 9th issue: J. E. McCloskey, R.R. No. 2, Fredericton, N. B.; G. O. Nobes, Milton, N. S.; J. H. Wood, Toronto, Ont.; and T. Hurst, Brantford, Ont. Mr. McCloskey won in the elimination test. In the June 16th issue the following forwarded correct lists: A. Dickworth, car foreman C. P. R., St. Thomas, Ont.; F. E. Regan, and B. Back, both of P. B. Yates Machine Co., Ltd.; H. T. Osborn, Ottawa; and B. J. Murphy, Can. Link Belt Co. Mr. Dickworth was the lucky paper to be picked out. One reader asks if we ever use our own advertisements in the contest. Sometimes we do, but not as a general rule.

CONTEST FOR JULY 7TH ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something that works in a Brass Sleeve.
2—A machine that indexes accurately.
3—Something which is effecting trade relations.
4—How to decrease operating costs.
5—Something being done for convenience of customers.
6—A case where it makes no difference what you need.
7—Something that is said to have set a new standard.
8—How to reduce costs ⅓ to ½.
9—A case where three seconds is sufficient.
10—Something that can be used wet or dry.
11—A case where a small amount of money can be spent wisely.
12—Something packed with wisdom and knowledge.

These are Correct Answers for List from June 16th Issue:

1—Dodge Mfg. Co. of Canada, Ltd.
2—Alfred Herbert Ltd.
3—Can. Ingersoll Rand Co., Ltd.
4—Hull Iron & Steel Foundries, Ltd.
5—The Walton Co.
6—Cleveland Pneumatic Tool Co. of Canada, Ltd.
7—Ford-Smith Machine Co, Ltd.
8—Brown & Boggs Co., Ltd.
9—Canadian Link Belt Co., Ltd.
10—Murchey Machine & Tool Co.
11—Canada Metal Co., Ltd.
12—L. S. Starrett Co.

Closing Date for This Contest is July 28th

DEVELOPMENTS IN SHOP EQUIPMENT

LARGE TURRET LATHE.

The Alfred Herbert Co., Ltd., with Canadian offices at 1 to 3 Jarvis St., Toronto, Canada, have placed on the market their No. 20 combination turret lathe. To enter into detail regarding this large machine is impossible in the space at our command, but here are a few important points worthy of consideration. Those particularly interested can secure further data in the regular manner.

This lathe is very large, having a spindle capacity of 7 in. The turret is provided with power traverse in both directions, and all levers and handwheels are of ample proportions being conveniently located. Oiling facilities, wherever possible, are automatic, and the coolant system has received close attention.

In the headstock all the gears are of steel, the main spindle gear being of high carbon steel, and the sliding gears are made from chrome nickel steel. All shafts run on ball bearings. The head forms an oil bath for automatically lubricating the gears, and there are 16 spindle speeds forward, and a like number on the reverse. Each headstock is put through a special running test before being used.

An 18" pulley, running on ball bearings and driven by a 5-in. belt is employed for driving, this pulley running at 400 r.p.m. Special suggestions are made for individual motor drive if desired.

No countershaft is required with this machine, and the headstock has a positive friction clutch drive. These clutches are of the expanding toggle friction type. In addition to this drive, the machine is provided with a positive drive which is intended to be brought into action when taking heavy cuts on large diameters. This drive factor consists of two hardened steel teeth let into the face of the right hand and heavy drive steel spindle gear.

The distance from the flange of the spindle to the face of the turret is 72½ in.; so that quite lengthy work can be handled. This machine has many other features which we cannot discuss at length, but sufficient to say that every detail has been carefully watched, even to the guarding of moving parts. Some idea of the machine's general proportions can be gleaned from the fact that the 25 in. chuck used, weighs 560 lbs.

HIGH SPEED SAW.

The W. Robertson Machine & Foundry Co., Buffalo, N.Y., have placed on the market a portable hack saw that is intended for either hand or power-drive. It can be used as a general utility saw in the shop when fitted up with two standard legs, while by removing the front leg it is suitable as a rail saw for use on street railways, where the current is taken from overhead. The electric current is ordinarily taken from a lamp socket, but where it is not available, the machine may be driven by hand by means of the lever shown lying in front of the saw, after connecting the lever to pins on the crank disc and on the frame.

The machine has a maximum capacity of 8 in. and uses 17-in. blades. The motor is mounted on a bracket supported on the bed and drives the crank disk through worm gears running in oil. Gravity feed is used, and a lever engaging a stud is provided for holding up the saw while clamping the work.

The latest model of the No. 2 power saw has a draw cut capacity of 6 x 6 in., and the machine has been equipped with an oil lift of the type employed on larger machines made by the concern and intended for relieving the teeth of the blade from the work on the idle stroke.

The oil-lift device consists of a two-cylinder pump submerged in oil contained in the tank shown removed and placed beneath the machine. One plunger is timed with the crankshaft, the other being connected to the saw frame. At the end of the cutting stroke the plunger connected to the crankshaft is on the down stroke, which forces the oil under the plunger connected with the frame, thus raising the saw from the work. At the beginning of the cutting stroke, the pump timed with the crankshaft has just passed a port allowing the oil to escape, thus allowing the frame to lower while on the cutting stroke. It is said that the lift greatly decreases saw breakage. The machine is equipped with a swivel vise for cutting angles up to 45 deg. It is driven through a friction clutch and stops automatically when the cut is completed.

CRANK PLANER.

The Woodward & Powell Planer Co., Worcester, Mass., have placed on the market a crank planer said to be particularly adapted to forge and railroad shop work such as die blocks, rod straps, cross heads and slide valves.

The machine has a short rapid stroke, and it is adjustable for length by a removable crank operating a screw in the crank disc. Any length of stroke up to 24½ inches can be taken over any portion of the table, the position of the stroke being adjusted by means of a shaft on the front end of the table. This adjustment can be made while the table is in motion.

For angular planing the head can be swiveled to either side for angular planing and is graduated in degrees. Feeds for cross, vertical and angular travel are operated automatically by power or by hand. The machine can be operated by one pulley connected to a 4-speed gear box or the pulley may be replaced by a gear driven by a motor mounted on top of the gear box. The handle for operating the starting and stopping clutch also operates a brake for stopping the table when the clutch is thrown out.

PORTABLE GRINDER.

The Black & Decker Co., Baltimore, M. D., have placed on the market a portable electric grinder that is said to give the operator entire control over the tool.

While this grinder is essentially a portable electric tool, it is supplied with detachable base and adjustable tool rest so it can be used with equal facility as a bench grinder. Besides the base the equipment also includes two 5" x 1" grinding wheels, one fine and one coarse, a wire brush wheel, and a rag buffing wheel.

This machine has grease lubrication throughout, forced air cooling, chrome nickel steel gears and shafts and aluminum alloy housing. The entire mechanism is protected from dust and other foreign matter. A desirable feature is the fact that these grinders can be operated on either direct or alternating current at will.

NEW DRILLING AND TAPPING MACHINE.

The Cinicinnati Hy-Speed Machine Co., Cincinnati, Ohio, have introduced to the market an automatic drilling and tapping machine. The machine is of the unit type construction, the clutch, brake and initial driving gear being a separate unit supported by the top bracket. Power is supplied from a single-pulley direct overhead drive and a dry plate clutch operating with an external clamping adjustable air-cooled brake. By a single handle directly in front of the operator, the machine is started and stopped. Spindle speeds are controlled by a handle on the side of the column. All pulleys are of aluminum.

ADJUSTABLE DIE HEAD.

The Geometric Tool Co., New Haven, Conn., have produced a new style self-opening adjustable die head. These heads were designed primarily for B. & S. automatic screw machines. but are quite as well adapted to other automatics.

This style die head does not depend on the turret feed, but floats to suit the thread being cut. This feature is said to prevent stripping and shaving of the threads, making the usual close camming of machines unnecessary.

A lever trip reduces the force of tripping the die head, and buffer springs allow the head to yield slightly when the chasers come in contact with the work, this insuring a good smooth thread from the start. Two check nuts at the side of head provide adjustment of the point of tripping.

No face plate is necessary, this making it possible to use projecting chasers where required for cutting close to a shoulder. A closing attachment is located in a convenient position to strike

a stop on the machine, this automatically closing the die head when the turret revolves.

The chasers are supported by hardened keys which are said to prevent tilting and consequent cutting of taper threads. Four chasers are used. The die heads can be fitted with suitable shanks to fit the machine they are to be used on.

UNIVERSAL MACHINE SHOP RULE.

The rule, termed a "Universal Machine Shop Rule," has recently been placed on the market by R. Poliakoff, 709 Sixth Avenue, New York City, who is also the designer and copyrightee of same. The purpose of the rule is to enable any shopman, machinist, foreman, draftsman, designer, estimator, etc., to determine quickly and accurately, without making any calculations, the different elements in his problems relating to machining a bar in a lathe or grinding it in a grinder. The rule is very simple and it is said to take only a few minutes to learn how to use it. The following problems can be solved with its aid, using only one side of the rule for the corresponding problem.

1. Given diameter of bar and cutting or grinding speed; to find the number of revolutions. 2. Given diameter of bar and number of revolutions; to find cutting or grinding speed.

3. Given speed in feet per minute and number of revolutions; to find diameter (in inches) that can be turned or ground. 4. Given length of bar in inches, feed in inches per revolution, and number of revolutions per minute; to find time (in miutes) required to turn (or grind) the bar.

5. Given depth of cut in inches, feed in inches and speed in feet per minute; to find volume of metal removed. 6. Given speed in feet per minute and feed in inches; to find the area machined.

NEW CATALOGUE AND NEW TOOLS.

A new small tools catalogue, No. 28, issued by the Brown & Sharpe Co., has just reached our desk. This book has been improved considerably over former editions and in it are shown some new tools and improvements to machinists' tools, all of which will no doubt interest machinists and tool makers alike.

Here are a few of the improvements. The tempered hook rules, No. 320, and the narrow hook rules, No. 325, now have a hook of a new design. The hook is reversible, small, and is provided with a shoulder to assist in setting calipers and dividers. It is held squarely and firmly on the rule by a screw and cannot pull off, and yet is easily removed to permit use of rule alone. There are no loose parts to be lost. These rules are very convenient for measuring flanges or circular pieces, through the hubs of pulleys, setting calipers, dividers and work of similar character.

An improvement has also been incorporated in the combination squares and sets furnished with the centre head. The centre heads are now ground so that both arms are of equal length and the extreme points are both equidistant from the edge of the scale. This permits the use of these centre heads with work of very large diameter.

The Vernier calipers, No. 570, and 571, have also been improved. These calipers, either in English or in Metric Measure, read direct, that is, outside measurements are taken from a Vernier one side of the measuring bar and inside measurements from a Vernier on the other side. No additions or deductions are required. This also applies to the 10" Vernier height gauge, No. 585. Points are placed on bars and slides of the Vernier calipers for setting dividers, etc. These calipers are also obtainable with an English measure Vernier on one side of the measuring bar and a Metric measure Vernier on the other side, in No. 572.

New Vernier height gauges, No. 585, are also shown. The base of this gauge is proportioned to give rigidity without undue weight and extends beyond the back of the bar which gives additional stability. The gauges are made in two sizes. The 10" size can be furnished in either English or Metric measure to take inside and outside measurements. It is also made as a combination gauge reading to English measure on the front and to Metric measure on the back. The 18" gauge takes measurements outside the jaws. The bar is graduated to read, by means of a Vernier, to thousandths of an inch or fiftieths of a millimetre as the case may be, the graduations in each case being carried far enough along the bar to allow measurements to the full rated capacity being made. The readings with the English measure of Metric measure gauge are direct.

A new Thickness Gauge, No. 644, with blades longer than those on the regular line of thickness gauges also appears in this new catalogue. This gauge consists of nine blades, 3" long and ½" wide, of the following thicknesses: .0015", .002", .003", .004", .006", .008", .010", .012", and .015".

A new vise for toolmakers and mechanics is also shown. This vise is claimed to be a handy tool for use in drilling, fitting and laying out work on surface plates. It is case-hardened and the base is ground. It is also said to be light and convenient to handle, being frequently held in the hand during operations.

No. 753, toolmakers' vise clamp, is also a new tool shown in the catalogue, obtainable now from stock for the first time. It is similar in appearance to the other vise just mentioned, but it is not provided with the V groove in the base or the tongue on the jaw and corresponding slot. These vise clamps are said to be very convenient for holding work to be drilled, etc., and are often used in pairs.

CLAMPING DOGS.

The Cincinnati Engineering Tool Co., Cincinnati, Ohio, have placed on the market a line of special dogs for use on first operation fixtures. Some of these dogs are adjustable, while others are of the stationary type. The adjustable style are made of case-hardened machine steel, while the stationary dogs are made of hardened alloy steel.

The advantages of the method of holding the work by means of the dogs are said to be as follows: The fixture can usually be designed and built very cheaply, due to the simple pattern and small amount of machining. The fixture is easily cleaned, as there are no projecting walls which hold chips in it. The work can be clamped close to the finished surface, which is especially advantageous when work has a large rounding and is difficult to hold in any other way. The ajustable dog positively clamps work down on the locating points, and does not cause the trouble incident to the use of a setscrew on which the point is slightly eccentric; that is, lifting the work from the locating points instead of clamping it down.

A SAW SET.

H. Hedstrom, who is car foreman for the C. P. R., at North Bend, B. C., has forwarded to us for inspection a model of an improved saw set which he hopes to soon patent and place on the market.

Canadian Banks Can Do Much To Assist Exporters

Importance of Adequate Banking Facilities—Methods of Financing Usually Classified Under Four Heads—Risk of Discounts—Question of Currency—Services Banks Can Render, and Other Points of Importance

"NO country is fully organized for export trade unless it possesses adequate banking facilities." These significant words, with their far-reaching meaning, were spoken by G. F. Towers, Superintendent Foreign Trade Dept. Royal Bank of Canada, in an address before the Canadian National Export Club at their recent organization meeting in Toronto.

"The methods of financing exports," he continued, "are usually classified under four heads: There is first the buyer who sends his remittance with his order. I am speaking purely from theory here, for I do not know of any such buyers, and I have never heard of any of them addressing mail to Montreal. There is next the buyer who obtains his goods on open account. This is mainly the case between buyers and sellers whose organizations are in some way connected. It may also be the case between people who have long done business with each other. I will not say any more about this method, because it is new business rather that we are all considering at the present time. We next come to purchases which are financed by the buyer establishing a confirmed letter of credit in favor of the seller."

"Now this is a very satisfactory method of doing business for any exporter. He is assured of receiving payment and knows if he conforms in detail to the requirements outlined in the letter of credit, that he will receive his money, and the transaction will be closed. Drafts drawn under confirmed letters of credit are cashed by the negotiating bank without recourse to the maker, who is thus relieved from all worry. The definiteness and unassailability of confirmed credits have received unmixed support from various high courts in the United States in recent cases, where buyers have endeavored to escape their obligations.

Normal Times Returning.

"Unfortunately in the normal times to which we are returning, only a proportion—probably a small proportion—of business is financed by means of these safe and attractive letters of credit. The financial end of the majority of export transactions is covered by drafts of the seller on the buyer, which the seller places with his bank on a collection or discount basis. Here we come right into the centre of the bank's functions in export trade.

"The main financial support given to exporters by the banks is through the medium of this discounting of the exporter's drafts on buyers in foreign countries. A certain proportion of drafts are sent through on a collection basis, but this involves the tying up of capital for some considerable period—a thing which most exporters do not want and cannot afford to do. If export business could only develop on that basis, then much export business would have to go by the board. We are taking stock at the present time of our facilities not only for keeping but for gaining new business during the years to come. What will Canadian banks do on the subject of discounts? What financial assistance are they prepared to give?

"I feel very strongly that the general ideas on this subject are not clear enough, and that everyone has not the necessary grasp of the principles which govern discounts—stamping one man's requests reasonable, another's unreasonable.

"Much trouble can come out of this. I know of one case where a Canadian manufacturer who had hitherto not undertaken any export business received a good order from a Latin firm in the South. Every bank report spoke favorably of this firm. The Canadian firm, therefore, accepted the order, and consented to draw at thirty days' sight. The goods required special manufacture. This was gone ahead with. Now we come to the unfortunate point in this transaction. The Canadian firm had not discussed the matter with its banker, who, when he was approached, was found to be unwilling to discount their draft. The Canadian firm could not understand it. They had read endless articles urging Canadians to develop export trade. They understood, and quite rightly, that the extension of moderate credit to buyers in other countries is necessary, and when their banker refused them his support, it seemed to them that one branch of our Canadian organization had failed them, and had left them in an exceedingly bad position. The answer is that the Canadian firm had overestimated their resources. Their domestic business was as large as they were entitled by their capital resources to conduct. And if, owing to their inexperience, or to the troubles which may arise in any transaction with a far distant country, the goods were refused, and the draft left unaccepted, the bank which had discounted it would have found itself in an unenviable position. True, the merchandise would have been under its control—but far off, and realizable on only at a loss which might degenerate into a sacrifice. And unless its recourse to the maker of the draft was productive of satisfactory results, this bank would find itself as creditor in a slow loan, instead of the possessor of a quickly liquidating security. It would be indeed lucky to come out of the transaction without a loss.

"Under whatever conditions discounts are made, some risk attaches to them. I do not care whether the bills are clean or documentary—whether the goods evidenced by documentary bills are staple merchandise or high-priced articles of luxury—the risk is there, though it naturally varies greatly. A bank will discount a client's documentary bills where it would not take his clean bills. It will discount his documentary bills covering wheat, where it would not discount them if they covered aigrettes or perishable foodstuffs. But it will never discount any draft unless the capital of the drawer warrants the assumption that he is able to stand any loss which might arise out of the transaction. There might be cases where a bank would not discount drafts to the full value of the goods, but would discount them if they represented only a certain percentage of the invoice value. This eliminates a certain amount of the risk. A bank discounts short term drafts more readily than long term drafts, for every day taken from the term of the draft lessens the chance of the occurrence of some unforseen event which would be productive of loss. A bank will discount drafts on good houses more readily than it will on those of less assured standing.

"But wherever we go, and whatever variations we find in the attractiveness of drafts from the discounting banker's point of view, we come back in the end to the fact that the client's resources are the bank's main security. Banks are trustees of their depositors' funds, and unless they are satisfied that they are incurring no undue risks they cannot let go of their money. I seem to have made a great many qualifications and reserves, but they are made for the sake of the clear understanding which is so necessary, and they should not obscure the fact that to the full extent of their powers Canadian banks are ready and willing to assist foreign business. I believe that the banking facilities that we enjoy in Canada in this respect are equal to any in the world. We have not the open money markets of New York or London, nor the rediscount facilities that some countries enjoy, but we have instead a centralized banking system which ensures that such funds as the country possesses

shall be available at the point where they are needed. And up to the present these funds have been adequate for our purposes. That being so, I do not think we have needed an open money market, one of whose chief virtues is that it attracts surplus funds from all over the country; in the case of the London market, from all over the world. No money market, however, will give up its funds for paper which does not bear the name of a firm with adequate resources. And anyone who could not discount his drafts with his bankers in Canada would find himself in no better position if he tried to sell his paper in New York.

"Misunderstandings are liable to arise on the subject of discounts, because opinions vary on the question of what legitimate requirements consist of. For that reason it is advisable for anyone who contemplates exporting, and who knows he will want to discount his drafts, to have a clear arrangement to that effect with his banker beforehand. Though this may seem obvious, the incident I have referred to a few minutes ago is witness to the fact that this procedure is not followed in all cases.

The Question of Currency.

"A rather controversial subject that I would like to mention is that of the currency in which drafts should be drawn. Many of our export transactions have been phrased in American dollars, and this has given rise to a certain amount of dissatisfaction among our customers. Certain importers abroad are familiar with the fact that a premium exists on United States funds in Canada and have a feeling that when they pay for a Canadian shipment in U. S. funds, the premium is an addition, and a considerable addition, to the profit of the seller. I believe that receiving quotations in American dollars is an advantage for them, and that if they clearly understood the situation they would not complain. England and the United States do a far larger business all over the world than we do, and sterling, and to a lesser extent United States dollars, are widely quoted and dealt in on all the exchange markets of the world. In any market where business is done on such a scale, you get quotations down to a very fine point. Now, if a drawee in a far-off country comes to cover a draft drawn in Canadian dollars, he is going to find, if he goes into the thing thoroughly, that the exchange rate which the bank will name is less fine than it could have given for sterling or U. S. dollars. The bank does not receive the up-to-the-minute quotations on Canadian exchange which it does on the others. Payment in one of the well-known currencies is entirely to the advantage of the buyer, and this fact should be emphasized.

"As far as the British West Indies and British Guiana are concerned, what I have just said does not apply, because Canadian bank branches in those places are naturally in an excellent position to sell Canadian exchange. To these places, then, our exporters should certainly send quotations in Canadian funds. The establishment of shipping connections between Canada and many countries of the world now makes it possible for our exporters to quote c.i.f. I am sure it is superfluous for me to point out how much more attractive it is for a prospective buyer to receive quotations c.i.f. his home port, rather than one f.o.b. some place or port in Canada. If he receives two reasonable offers, one c.i.f., the other f.o.b., it is ten to one that he will take the former, since he knows exactly what that is going to cost him, and does not have to waste time in figuring out the cost, insurance and freight from Canada to his country.

Services Banks Can Render Exporters.

"The next branch of the subject I have in mind is the service which banks can render exporters. First and foremost is the service of effecting collections. There is as much difference between good and bad collection service as there is between black and white. An exporter who entrusts his documentary drafts to a bank wants to know that they will be instantly forwarded to destination, and promptly presented for acceptance or payment; and especially he wants to feel that, if the draft is unaccepted or unpaid, the bank will deal with the goods intelligently according to his instructions, or cable for instructions where none have been given. If good service is not given in these cases, an exporter is liable to hear, some weeks after, that his draft is unaccepted, his shipment refused, and his goods lying on the dock incurring charges. I do not think Canadian exporters are liable to have things like this happen to them. Where Canadian banks have no branches they usually have excellent correspondents. I feel I must refer especially here to the British Empire. In every country of the Empire, Canadian banks either have branches or they have as correspondents the strongest and most prominent banks of the country concerned. This is important, because we are probably looking more to the wide fields of the British Empire for new markets than we are to any other territory.

"Another and very important service rendered by banks is the provision of credit information on foreign firms. No export shipment which calls for any extension of credit can be made to an unknown house. And it is undoubtedly most satisfactory to have the report on the prospective buyer come from a source which can be looked on as reliable, and whose views on strength and security can be regarded as conservative and coinciding with our own. The Canadian banks which have foreign branches abroad are naturally in a peculiarly good position to render credit information service covering the countries in which they are established. I do not want to stress any one bank too much, but I have to refer here to the information that the Royal Bank has on firms in the British West Indies and British Guiana, territories with whom this country has concluded a broad preferential agreement, and with whom we are conducting a steadily growing trade. In the Royal Bank we have reports on the vast majority of these firms already in our files, and it needs only a request to have us obtain full information on others. The Bank of Montreal, through its affiliation with the Colonial Bank, and the Bank of Nova Scotia, and Canadian Bank of Commerce through their branches, are also in a position to give Canadian exporters service in this respect. In general, your banks can obtain good credit information for you in regard to most firms in the world.

Information Department.

"The last branch of service I want to discuss is a more or less recent development. I refer to the establishment by the leading banks of special departments of information and service. In the United States and England they are very strong on these, and have found them exceedingly useful. Their advertised functions vary. For some you will see that they can supply the names of buyers in foreign countries, can give data on foreign markets, tariffs and conditions, and do various other things. I am of course prejudiced, but I think the best system is the one which avoids as far as possible giving lists of names, but tries instead to place sellers only in touch with buyers who would be interested in hearing from them. If a firm comes to us and says that it wants to sell such and such a thing in the British West Indies, or South America, for example, we give them our opinion on the possibilities, and we have our manager in the South get in touch with firms there, not to make any definite arrangements—for that is impossible—but to find out if the local firms are interested in hearing from the Canadian firm. If the matter is an urgent one, we can usually suggest some names without writing South, but anyone who is seriously thinking of commencing export business can usually afford to wait the few weeks which a letter and reply require. In general, we are prepared to render any reasonable service and fulfill any request. When I say reasonable, I mean almost anything, because we have not yet found that anyone has asked us something which

The Adolescent Attendance Act

THE Adolescent School Attendance Act is something which interests, or should interest, every Canadian manufacturer. Those responsible for the enforcement of the act have shown good judgment, for it will be brought into force by stages, and not at one wild jump.

Speaking on Section 3 of the act, which comes into operation on Sept. 1st, 1921, and which provides for the attendance at school of adolescents between "14 and 16 years of age," the minister announces that in conformity with this Section of the Act, pupils are expected to remain in full time attendance at school until they are sixteen years of age, unless employed on the authority of a home permit or an employment certificate as provided for by the Act, but that it is not his intention to instruct Attendance Officers to make the Act retroactive by endeavoring to compel young persons between 14 and 16 years of age who have been engaged in regular employment to return to school. School authorities, accordingly, will in the beginning be charged with providing only for the continued instruction of those who are at present at school, and not for the numbers who might be forced to return to school by the strictest interpretation of the Act. At the same time, he expects that the Act will be made fully effective to the extent that attendance officers will be appointed according to law and their Departments organized to ensure: 1.—That all young persons between 14 and 16 years of age shall be either at school or at work; 2.—That all those who are at work either at home or in gainful employments shall hold the permits or certificates required by law.

Section 9 which provides for the establishment and maintenance of part-time courses of instruction for young persons at work comes into operation on September 1st, 1922. The Minister expects that boards will be prepared to make this section effective on that date.

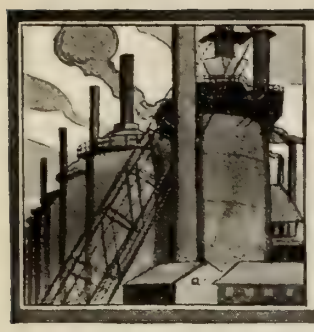
The enforcement of this Act, should without question, raise the standard of the young manhood leaving our public schools. The period between 14 and 16 is an extremely dangerous one, and with the influence of good leadership, our boys should leave the various halls of learning in a much better educated state at 16 than could possibly occur two years earlier. There may be a few who consider the terms of the act too strict, but these are sure to be in the minority.

Management Problems

THE difference between success and failure in business, especially in manufacturing, is often found in the presence or absence of some comprehensive plan of management. One would hardly start on a trip to the North Pole, unless many advance plans had been made regarding suitable clothing, provisions, etc., etc. It is a long jump from the North Pole to the manufacturing field, but the same condition holds good. If you want to produce some article successfully, and at a good profit, you must first lay your plans. Every operation must be studied out ahead of time. You must visualize the product passing through the plant, and wherever possible eliminate wasted effort. Even the routing of the part must receive careful consideration, for when a product is moved willy nilly all over a plant, the trucking expense mounts accordingly.

Standardization is perhaps the most important of all factors, for many dollars can be saved by designing the parts in such a way as to use them on various machines which you may be turning out. Then again, a part may be designed in such a manner that it can be produced on a disc grinder instead of a miller or planer, this relieving the larger and more expensive machines.

Shortage of certain parts must also be avoided. Nothing causes a drop in efficiency so quickly as a shortage of work. The operators instinctively slacken their efforts, and production drops.



A master schedule should be prepared, and this followed out as near as possible. True, there may be slight deviations from the original, but no schedule made was yet perfect. The routing from the raw material entering the plant to the assembled product should be watched carefully, and if the plan has been mapped out intelligently, profits should show a decided increase.

A writer recently stated that to his mind such a master schedule as we speak of should be prepared in the office of the president, and where the gentleman holding this position is a practical man, we believe the idea an excellent one. Should the president however, be a business man only, he should see to it that the heads of his various mechanical departments are called in for consultation on the preparation of the schedule.

Aeroplane as Business Help

THE Aeroplane as a business help is becoming more common every day. At first, a few firms, after some sensational publicity, used an aeroplane to deliver spare parts for some machine or automobile in a hurry, but at best these incidents could be considered stunts.

A few days ago a contractor in Vancouver arrived at his office to find that he had until noon of that day to submit figures to be in the running for a big building contract. These figures, or at least the majority of them were in the hands of his partner, who was quite a distance from Vancouver, in fact was 68 miles north of Squamish, a place with no telephone communication. An aeroplane was brought into service; he got to his partner and returned with the figures before noon, incidentally receiving the contract. This may have been a stunt idea too, although it does not look like it, but in any case the usefulness of the aeroplane as a speed factor in business is clearly proven.

MARKET DEVELOPMENTS

Market Has Reached Bottom. Improvement Expected

When Things Get So Bad That They Cannot Get Any Worse—Well, Improvement Is Bound To Come. Orders Are For Small Amounts—Fewer Mills Have Closed Entirely Than Was Expected.

THE market has reached the stage where it is impossible to report any fresh dullness. July, as a rule, is one of the dullest months of the year in the steel market, but conditions during the past three months have been so poor that things cannot get any worse. The trade is rather glad that bottom has been reached, for when things cannot get any worse there is always a hope for improvement.

The Steel Corporation is operating at about 30 per cent., but it is impossible to give a close estimate on the independents, as each producing company is in a class by itself. Plant operations vary greatly from week to week. The best guess for the independents seems to be between 10 and 15 per cent.

Fewer mills have closed entirely than was expected. Most plants would lose less were they to cease work, but luckily the desire seems to be to give workmen as much employment as can be found for them. The plants that are entirely closed are chiefly small plants, having no orders at all.

A small lot of basic pig iron was sold by one steel interest to another at $20.00 furnace. Bessemer remains at $22.50 valley, a price established on single carloads. Inquiry for a larger lot would no doubt bring out a lower quotation. Foundry iron has dropped another 50 cents, being now quoted at $21.00 valley. Foundry coke is $4.25 to $5.00, depending on brand. Sales at the latter price are rare.

PITTSBURGH FEELS THAT BUSINESS HAVING REACHED BOTTOM WILL NOW IMPROVE

PITTSBURGH, July 7.—July and August are normally by far the dullest months of the year in the steel market. Now July comes without bringing any fresh dullness. Every week for two or three months past has brought reports of greater and greater inactivity, but now the trend seems to be broken. Of course one might rejoin that the steel market had grown so dull it could not get any duller, but that was just the condition the trade was hoping would develop, or when things cannot get any worse they are likely to begin getting better.

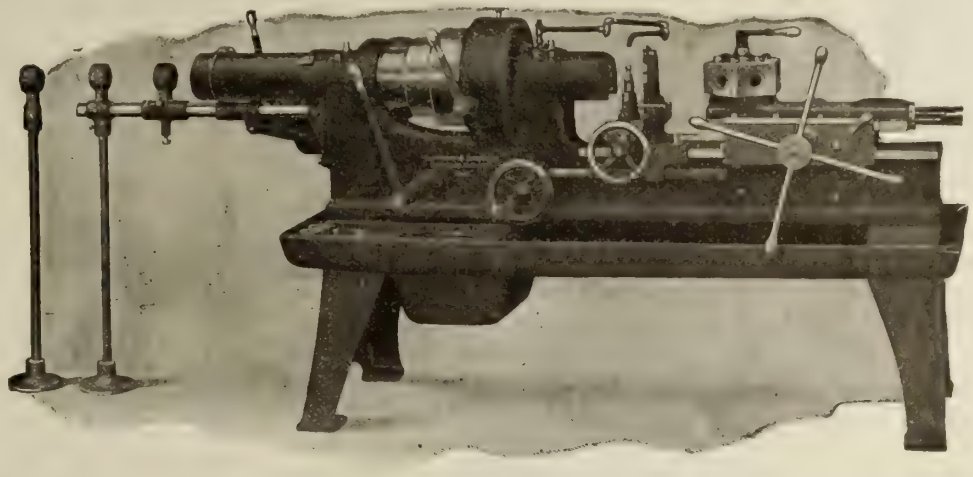
As to mill operations, moreover, it is doubtful whether they have grown any leaner. The Steel Corporation is said to be operating at about 30 per cent., and the corporation had such a rate early in June, there being afterwards a slight improvement. It is impossible to estimate very closely the rate of operation by independents as each producing company is in a class by itself, while at a given plant operations vary somewhat from day to day and greatly from week to week, so that it is difficult to strike an average even for a single plant. The best guess for the independents seems to be between 10 and 15 per cent., not that many plants actually operate at such a rate at a given time, but that there is complete idleness at times to balance operations at other plants or at other times at 20 or 30 per cent. This would give an operation for the whole industry of about 20 per cent., wihch would mean a rate of steel ingot production of about 10,000,000 tons a year. It does not look as though the rate will go below this.

Fewer mills have closed entirely than was expected. Most plants would experience less loss in closing entirely than in operating at present low rates, but it is desired to give the workmen such employment as can be found for them. Plants that are closed entirely are chiefly small plants, having no orders at all. Operating plants may close for a week or two at a time, as the supply of orders dictates.

Steel Prices.

The trade takes less interest in prices that may be going at the moment than in prospects for the future. Everywhere it is recognized that within a short time the market on an average will be well below the April price schedule, and it is thought that this is going to be the final shake-out in prices, at least for a few months or until there is a further and material reduction in costs. Prices made now are of interest chiefly by way of the possible suggestion they contain as to prices in future.

Naturally the Steel Corporation is the subject of rumors, as to what the corporation will do at this time or that. A favorite prediction lately has been that the corporation would reduce prices and wages about July 15. This may prove correct, but the prediction fails to take account of one very distinct possibility, that the Steel Corporation may for a time have not set prices at all, and if it has no set prices it has nothing to announce. There have been short periods in the past when the corporation had no regular prices, but made a quotation on each inquiry as it appeared, suiting the price to the desirability of the order.



As a matter of fact, it is a question whether as to certain products the Steel Corporation has regular and rigidly maintained prices at the present time. The reduction in wire products of $5 a ton over a month ago and the reduction of the same amount in sheets a fortnight ago were not announced as specifically establishing the new quotations as regular prices.

Independents have been doing more shading in the past week, some of the low quotations being made only against specific inquiries, not representing re-

Warner & Swasey Screw Machines

For large output and close limits—If you are figuring on screw machine work you can depend on W. & S. machines being right for the job.

WINNIPEG, VANCOUVER

If It's Machinery—Write "Williams"

64 Front Street West
TORONTO

HENDEY

THE ability of a machine to do its work well depends upon more than its various labor-saying attachments. It is governed to a large degree by the fitting, assembling and aligning of the various parts.

A careful and well rounded series of tests is made on each Hendey Machine before it is passed for shipment.

One of these tests — testing alignment of spindle with ways of bed on a Hendey Lathe—is shown on the left. A limit of variation of .0005 is allowed; but very seldom reached, between collar at nose and the one at outer end, and it must show large at outer end to offset possible spring of bar away from tool, and to favor hole in any boring operation running small at spindle end.

LATHES—MILLERS—SHAPERS AND CENTERING MACHINES

ductions that the maker would apply to all inquiries. There is a report, which may be correct, that the Inland Steel Company took 7,000 tons of plates for tanks for the Sinclair Oil Company at 1.85c Chicago, when the April price was 2.20c, Pittsburgh, and the carload market of late has been quoted at 2.00c, Pittsburgh. Some of the low quotations made lately have perhaps been by way of experiment, to see if much additional business could be brought out by lower prices. The Steel producers have been claiming that price reductions would not stimulate business, in conditions such as have obtained, but that at some time a disposition to buy would develop, and then price reductions would help.

After occasional sales of galvanized sheets had been made at 4.50c, when the recent reduction put the price at 4.75c, one mill announced 4.50c as its regular quotation, and others have been following. This leaves black at 3.75c, making a spread of 75 cents per 100 lbs., the lowest spread on record, but zinc is at a lower price than at any time since 1908.

Soon after the reduction of $5 a ton in wire products, making plain wire 2.75c and wire nails $3, base, the spread for galvanizing was reduced from 70 cents to 50 cents, so that galvanized wire is now 3.25c, while with painted barb wire at 3.15c galvanized barb wire is 3.65c. Woven wire fence has been reduced 2½ points, equal to about $5 a ton, the new discount on carload and larger lots being 65½ per cent.

A steel interest in the valleys has sold a small lot of basic pig iron to another steel interest at $20, furnace, or 50 cents under the previous sale, and the market is now quotable at $20. Bessemer remains quotable at $22.50, valley, a price established on single carloads. Inquiry for a larger lot would no doubt bring out a lower quotation. Foundry iron has slid off another 50 cents, being now quotable at $21, valley.

Sales of Connellsville furnace coke to blast furnaces have been rare. Recently the market declined from $3.10 to $3, on sales of single carloads to miscellaneous consumers. Since then a sale of about 3,500 tons has been made at $3. This was to a furnace that had shut off shipments on a contract but desired to run another week before blowing out. Foundry coke is $4.25 to $5, depending on brand, sales of the brands held at $5 being very rare.

TRADE GOSSIP

The Ontario Legislature has voted $1,000,000 to provide for the erection of a provincial cement plant. According to F. C. Biggs, Minister of Public Works, it is intended to proceed with the erection of a one-unit plant having a capacity of 300,000 barrels a year. The object is to supply cement at cost for municipal development, but if the municipalities for any reason fail to place their orders with the Government, the provincial works would be capable of absorbing the total output of the factory, since it requires this amount each year to resurface roads. It is estimated that the municipalities outside of Toronto require from 200,000 to 300,000 barrels of cement a year, while in the city from 50,000 to 60,000 barrels are used annually. If the demand justifies it, the new cement plant can be extended into a two-unit one with a production of 700,000 barrels a year.

It is not the intention of the Government to enter into competiion with private concerns on the open market, but it desires to provide a reliable source of supply for municipal and provincial needs. The location of the plant has not yet been settled.

POINTS IN WEEK'S MARKETING NOTES

No fresh dullness can be reported, and as things have hit the bottom, improvement is looked for by the trade generally.

The Steel Corporation is running at about 30 per cent., while the independents are more around the 10 to 15 per cent. mark, although these latter figures cannot be quoted as authoritative because conditions in the various companies vary so much from week to week.

Fewer mills have closed entirely than was expected. Although most plants would experience less loss in closing, than in operating at present low rates, there is a desire to give the men as much employment as possible.

There is a rumor that the Steel Corporation will reduce prices and wages about July 15th. So far this is only a rumor and certain important factors have not been taken into consideration.

Sheets are dropping, black being 3.75c. Zinc is at a lower price than at any time since 1908.

A small lot of basic pig iron has been sold for $20.00 furnace. Bessemer remains at $22.50 valley, this price being established on single carloads. It is thought that a larger enquiry would bring out a lower price than this.

The market for Connellsville furnace coke has dropped from $3.10 to $3. Foundry coke is $4.25 to $5.00, the sales on the latter being very few and far between.

Big cuts in British iron and steel prices are announced. Scottish malleable iron has been reduced three pounds a ton but a comparison with the Belgian price shows that the British ore is sixteen pounds against £9 15s., while other continental and American steel makers are quoting pounds lower a ton than the British. It is expected that there will be another drop in the British price now that the coal strike has been settled.

Kingston Public Utilities Commission is going after the firm of Davis and Farnum, Waltham, Mass., in the United States courts to recover about $7,000 which the local commission through an error overpaid the American gas tank contractors on a big job done at Kingston last year. The company admitted the overpayment but has presented a revised bill, and offers $1,600 in settlement, which the commission refuses to accept.

The Northern Aluminum Company, Shawinigan Falls, Que., have received an order for seven hundred miles of three-quarter-inch aluminum steel reinforced cable, from the Victoria (Australia) State Electricity Commission, according to the weekly bulletin of the Department of Trade and Commerce. The line comprises six separate wires, hence the large amount required. It is anticipated that the whole quantity will be delivered in Melbourne by the end of the year.

Mr. A. J. Hollis, managing director, Bevan, Churchill Co., Ltd., merchants and bankers, London, England, says that his company are anxious to get in touch with Canadian manufacturers of agricultural implements with a view to representing them in Europe. This concern has a branch office in the Bank of Nova Scotia Building, St. James St., Montreal, and those interested should write Mr. F. M. Raphael, who is manager at this Canadian office.

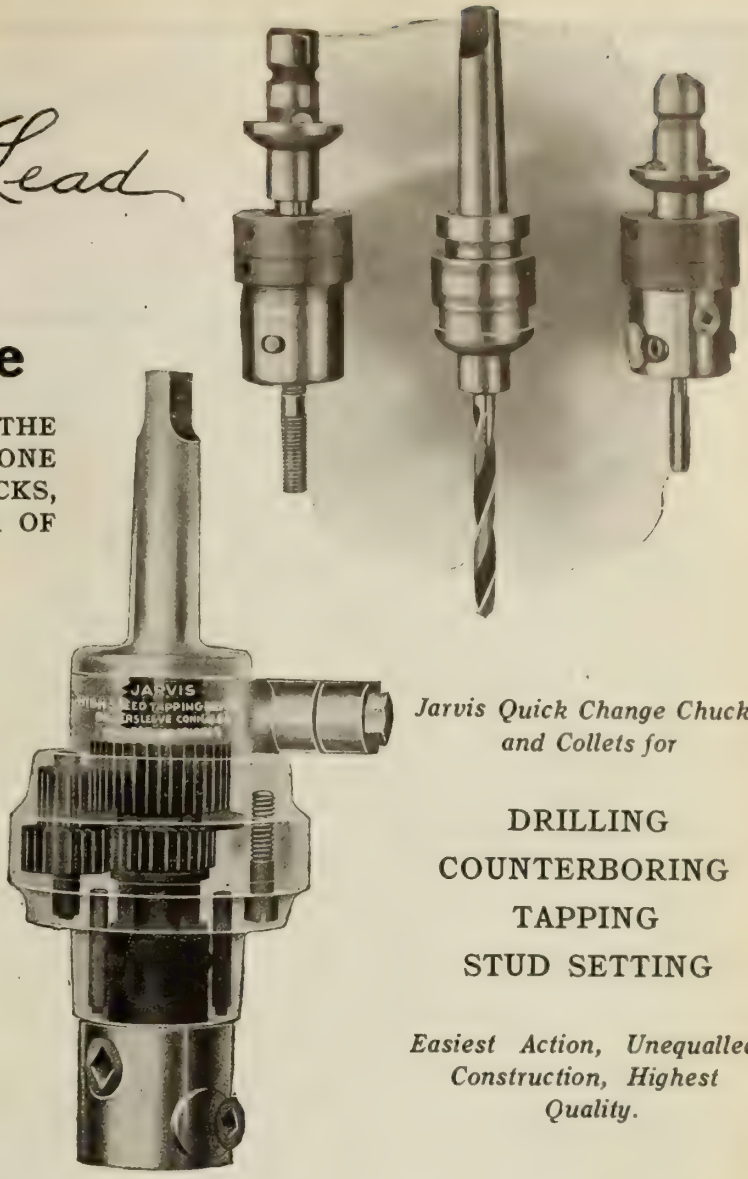
The Canadian Association of Stationary Engineers concluded their 32nd annual convention at Ottawa on June 30th. The following officers were elected for the ensuing year:—Past President, R. O. Leach, Toronto; President, F. Harper, Kingston; Vice-President, H. Wright, Montreal; Secretary-Treasurer, L. J. Ellis, Hamilton; Conductor, G. F. Galloway, London; Doorkeeper, R. E. Rodney, Ottawa.

At a special meeting of the Canadian Consolidated Rubber Company, Limited, approval was given to an increase in the number of directors from fifteen to sixteen and some changes were made in the personnel of the board. R. E. Jamieson retired from the board at his own request and was succeeded by J. A. Connor who will be director in charge of sales.

The additional place on the board was filled by the election of George W. Charles as director in charge of manufacturing. The two new directors have both been connected with the company for some years.

The Dominion Government has placed an order with the Algoma Steel Corporation, Ltd., for 50,000 tons of rails, which will be used on the Canadian National Railways. The plant at Sault Ste. Marie is busy at work, two thousand hands being employed. It is estimated that the work will take about two months to complete.

Right on the Lead



Make a Turret Lathe of Your Engine Lathe

JARVIS COLLETS CONVERT AN ENGINE LATHE INTO A TURRET LATHE BY SIMPLY USING ONE OF THE JARVIS QUICK CHANGE CHUCKS, WHICH ALLOWS THE USE OF ANY NUMBER OF DIFFERENT TOOLS.

Acquaint yourself now with Jarvis High Speed Tapping Devices and Quick Change Chucks and Collets

The booklet will be a worthy addition to your Mechanical Library—It is interesting—It is free—It is yours for the asking—

The Jarvis High Speed Tapping Device is superior to any other. It has a ball drive and ball reverse, making easiest action, with no clinching or binding. Reverse motion faster than the drive. Specially designed Chucks make special taps unnecessary. Tap breakage reduced to the minimum. It makes no difference whether the tap is forced against the work in a Drilling Machine, or the piece is pushed towards the tap in a Speed Lathe. Two Styles of Chucks. Seven Sizes of Tappers. Range of Tapping from 0 to 2″ inclusive.

Jarvis Quick Change Chucks and Collets for

DRILLING
COUNTERBORING
TAPPING
STUD SETTING

Easiest Action, Unequalled Construction, Highest Quality.

Jarvis Tappers and Quick Change Chucks and Collets are Developed to such a degree of perfection that the Geometric Tool Company recommends and furnishes them as a fitting adjunct to their line of Threading Tools.

Where one hole is drilled, reamed, counterbored, tapped and a stud set, or any two of these operations are done with one spindle, the Jarvis Quick Change Chucks pay for themselves in a very short time. Changes are made without stopping the Drilling Machine or Lathe.

There is no burring from constant use to interfere with the easy entrance or operation of the Collet.

Jarvis Quick Change Chucks and Collets consist of a chuck or locking member and a sufficient assortment of Collets for any job. Any Standard Drill Chuck can be fitted to the Morse Taper Collets.

Combination Tapping Device and Quick Change Chuck

In place of the regular chuck, the Tapping Device is equipped with a Quick Change Chuck, forming a Combination Tapping Device and Quick Change Chuck. This is the combination much in demand.

METRIC SYSTEM NOT IN FAVOR

Introduction and Adoption of System a Different Matter. Not the Success Some Advocates of the System Would Have You Believe.

"Commerce Reports" as far back as June 29th, 1920, printed a report from Constantinople by Consul General Randal on the "Use of the Metric System in Turkey."

In view of the present agitation for the compulsory use of this system of measurement, some parts of the report are of timely interest to both manufacturers and machinists. According to figures the Turkish Government adopted the metric system as the official standard in 1915. The date is significant, for at that time German influence was paramount in Constantinople.

Evidently it was the desire of the Government to make this the exclusive system of weights and measures, but so far, outside of official circles, the metric unit is little used. In fact, in the interior, the system is practically unknown, and it is doubtful if it will be popularly accepted for many years to come, if at all. The people find the new system very much simpler from a mathematical point of view, but its units are meaningless to them until converted into the units of the old system, for the decimal system as applied to potatoes or sugar cannot be kept constantly before the mind as can the decimal system as applied to money. It is therefore infinitely more difficult to learn and the attempt to introduce it has been productive of no little confusion.

The question may be asked: How can the people find the new system much simpler if to them the new units are meaningless? It is noteworthy that the "adoption" of a new system is by no means equivalent to its "introduction." Emphasis is laid on a long transition period; the words "if at all" sound rather hopeless. The difficulty of becoming sufficiently familiar with the system, in order to use it, is brought out and the "confusion" caused by the use of two systems is emphasized.

INTENSIVE SELLING CAMPAIGN PLANNED

A significant step after business has been taken by the formation of a so-called "Sell Now League." This campaign is in the interest of intensive selling and it is hoped to enlist every manufacturer and merchant in the U. S. for the purpose of spreading the doctrine of selling as an economic aid at the present time. The committee includes Francis H. Sisson, vice-president of the Guaranty Trust Company; Senator Nathan Straus, Jr., Joseph P. Day, Jules Bache, Senator Arthur Capper, John Willys, president of the Willys-Overland company; E. C. Patterson, president of the National Cash Register Company; B. C. Forbes and J. Mitchell Thorson, chairman.

Here is an idea that could well be adopted by Canadian manufacturers in general.

GERMANY CAN UNDERBID CANADA

Machine Tools Can be Made in Germany For Less Than in Canada, Britain, or United States. Reasons are Shown.

It is now a recognized fact that Germany is underselling both Britain, Canada, and the United States in outside markets, notably in machinery. How can they do it?

The First Federal Foreign Banking Association points out that in the five chief elements in the price of a manufactured product Germany has the best of its competitors. These are:—Raw materials; labor; capital; management; overheads, and profits.

The following tables, which were based on conditions in Germany last fall, tells the story. The figures are given in marks, converted into gold on the basis of dollar exchange.

	Wages Per Week.* Marks.		Dollars.

*Nine-hour day in 1913; eight-hour day in 1920.

The German Government controls prices, and has a bureau in which is combined the control of exports and imports, with the control of exchange. The mark in domestic exchange is kept upon a basis of its own, and the foreign trade value of the money is negotiated on a different basis. It is plainly apparent that Germany is employing a subtle, new kind of protectionism in her foreign trade.

The Germans, individually and as a national unit, seem to be capable of self- discipline to an extent unapproached by any of Germany's trade rivals. German laborers, both before the war and now, were willing to work for less, and German capitalists were willing and are willing to take less by way of profits, than are either British, Canadian, or United States manufacturers.

A SUGGESTION WELL WORTH WHILE

A member of the Canadian Manufacturers' Association deserves considerable credit for an excellent suggestion with regard to long distance telephone serice. It is to the effect that all business establishments should print their telephone number conspicuously on all letterheads and advertising matter going out through the mails. In making long distance calls an extra expense is entailed if the telephone number of the party called is not given, so that it is apparent that a saving of time and money would be effected were the practice generally adopted of printing numbers on letter paper. Some firms already do this but many do not and it would be a helpful thing if all would adopt the suggestion.

EXPORTS FROM CANADA TO BRITAIN INCREASE

Outgoing Trade for May Greater by $3,000,000 Than for Same Period in 1920.

According to the weekly bulletin of the Department of Trade and Commerce, Canada's exports to the United Kingdom exceeded by $3,000,000 those of May, 1920.

They point out that, while Canada is experiencing, with other countries, the excessive reaction in business, still her export trade has not diminished in nearly the same proportion as her imports. Furthermore, in considering the declines from 1920 figures, the bulletin states that it is necessary to remember that the value of the dollar is considerably higher in purchasing power to-day than this time last year, so that the slump is not so ominous as it appears at first sight.

The returns of the United Kingdom and the United States tell the same story—a period of reaction after the extravagant buying in the months succeeding the war.

ERRATA.

On Page 41 of the June 2nd issue there was an article referring to a twist drill grinder. It was stated that this machine was brought out by Wilmarth & Mormon. This latter word should have been Norman, not Mormon.

STANDARDS CONFERENCE

Unofficial Meeting in Regard to International Standardization of all Engineering Products.

A conference, which although unofficial in character, should have a far-reaching effect was held recently in London, England. The secretaries of the various standardizing organizations got together with the permission of the main committee of the British Engineering Standards Association, and the object of their meeting was the exchange of ideas, looking towards the establishment of closer relationship.

Each secretary gave a brief report of the general organization of the work in his own country, the methods adopted in arriving at the standards, and also the principles followed to ensure their adoption when issued. It is interesting to note that in most countries it is becoming more and more recognized that industrial standardization, whether of quality or dimensions, to be really useful must be arrived at through a process of unifying the needs of industry rather than by attempting to set up an ideal. It also appears that whereas engineers are everywhere giving freely of their time and experience to this important work, its value to commence generally is far too little appreciated, and is therefore not being supported financially to the extent that it should be.

"Some enthusiasts," says R. G. Durley, who represented Canada at the conference, "are rother apt to think that the time has arrived to attempt to create an international organization for standardizing all engineering products, but the conference took a much more modest view, and seeing the almost insuperable difficulties in the way, preferred to see international standardization develop along national lines and sectionally, as in the case of the now well established International Electrotechnical Commission.

The conference had no executive functions whatever, but each secretary will in due course submit to his respective organization the suggestions of the conference on the various points discussed.

The secretaries were entertained by the British Engineering Standards Association during their four-day conference.

"The human factor enters so largely into all questions of standardization," says Mr. Durley, "that for the secretaries of these important bodies to meet and become personally acquainted and thus have an opportunity of comparing notes in this informal way, is bound to be of no small advantage in the future, and materially assist in guiding international intercourse on this complex question along right lines."

STEEL BUSINESS VERY QUIET AT PRESENT

Roy M. Wolvin, president of the British Empire Steel Corporation, just back from a two months visit to England, stated recently that until such time as the world demand improved to such an extent as greatly to exceed the export surplus of Germany and Belgium, the steel export business of other countries would be negligible.

In regard to the British Empire Steel Corporation, he said results of operations for the second quarter of the year would show material improvement over the first quarter and that generally there seemed to be a tendency towards improved conditions. A very satisfactory coal business, he said, was expected in July.

NEW FACTORY

Bowden Bros., Toronto, are establishing a factory on Primrose Ave., for the manufacture of belt dressing, rope filler, etc. It is hoped to have this plant in operation about the first of June, with about six employees. Different grades of dressing for transmission and conveyor belts as well as rope filler for drives will be made. J. William Bowden, and C. Wilson Bowden are the members of the firm. The former will be sales and general manager, and the latter will have charge of manufacturing. One ton a day will be the plant's capacity.

MARINE NEWS

The death occurred at Port Credit on July 2nd, of William Newman, who for a number of years sailed on various lake boats. Death was due to heart failure.

Tug Joseph L. Russell. formerly the passenger steamer Lakeside, which plied between Port Dalhousie and Toronto for many years, carried away both head gates of lock 12, Welland Canal, on July 2nd, causing damage estimated at $9,000.

The British freighter Antrim, said to be bound from Montreal for a United Kingdom port, run aground in a dense fog at Bay St. Lawrence, Cape Breton, while on her way to Sydney for bunker coal, on July 2nd.

The single screw cargo steamer. "Canadian Engineer," one of the fleet of the Canadian Government Merchant Marine, was launched by the Collingwood Shipbuilding Company from the Dominion Shipbuilding Company's yards at Toronto on June 30th. The christening ceremony was performed by Mrs. J. H. Porter, in the presence of a large number of Toronto citizens.

A conference of the Institution of Civil Engineering was held on June 29th at London, England, to present the John Fritz medal to Sir Robert A. Hadfield, for the invention of manganese steel. A number of prominent American engineers were present. The medal is the highest honor awardable by the American engineering profession.

LOCOMOTIVES BEING MADE IN SWEDEN

According to Swedish Export, the Munktell engineering workshops at Eskilstuna is going to co-operate closely with Nydqvist and Holm's locomotive works, Trollhattan. Some time ago the Trollhattan works received an order for 1,000 locomotives from the Soviet Government. It is in conjunction with this and other orders that the co-operation has been effected. Part of the Munktell works is consequently to be adapted for locomotive building; it is also announced that the interests which control Nydqvist and Holm have largely been able to extend this control to Munktell.

PERSONAL

Mr. David Ewart, for many years chief architect of the Federal Public Works Dept. at Ottawa, died recently, at the age of 80 years. Mr. Ewart was born in Scotland and first entered the public works department 50 years ago.

Hon. Edgar M. Rhodes, speaker of the Canadian House of Commons, has been appointed president and managing director of the British American Nickel Corporation, and he will undertake the re-organization of this concern.

The city of Kitchener, Ont., is considering the appointment of an assistant city engineer.

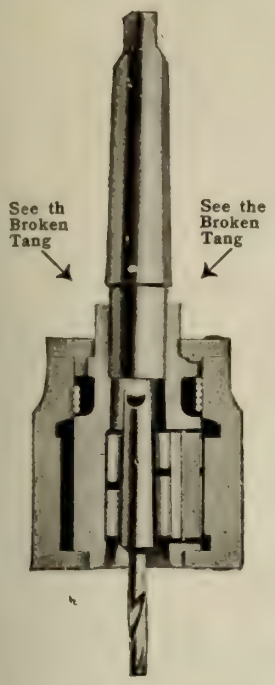
The death occurred recently of Mr. Aubrey G. Robb, who for more than 20 years has been superintendent and chief engineer of the Robb Engineering Works, Amherst, N.S. Death was due to bloodpoisoning. Deceased was secretary of the Maritime Branch of the Canadian Manufacturers' Association for some years.

THE PIG IRON OUTPUT

According to recent reports the total output of pig iron in Canada during the month of March was 60,433 long tons, an increase of 2,700 tons over February.

TRADE GOSSIP

The Transportation Commission has purchased for $25,000 from John Harris and Co., a lot, 237 x 135 feet, on the west side of Coxwell Ave., Toronto, north of the G. T. R. for railway yards and siding purposes for handling materials. After checking up the tender of $350,000 for rails awarded to the United States Steel Products Co., and finding that, owing to the exchange rate, the tender is not as advantageous as expected, the contract has been awarded to the Consolidated Steel Corporation at Bethlehem, Pa. The order for intersection track work goes to the Canadian Steel Foundries, Ltd., Montreal, at $50,000. Canadian firms, in so far as possible, will receive contracts for ordinary and special ties, amounting to about $90,000. All new civic cars are to be painted a rich wine color.



After careful consideration of the case, Judge Coatsworth announced the verdict of "guilty" in the case of Allis-Chalmers, Ltd., charged with criminal negligence in the management of a crane and bucket, which prematurely dumped a quantity of sand on George Hearst, a worker in the foundry, killing him. The counsel for the defendant company, W. K. Murphy, was granted the right to ask for a stated case for argument in the Court of Appeal. Meanwhile the judge imposed a fine of $1,000 staying execution until October to allow of the argument of the stated case.

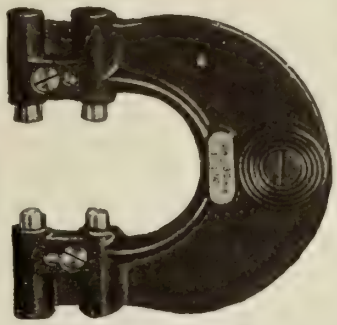
It was decided that next year's convention would be held in Kitchener, Ont.

Tenders will be received, no closing date set, by Geo. K. Dewey, City Clerk, Brockville, Ont., for construction of a steel bridge.

A tannery is being built by Geo. G. Potvin, Metabetchouan, Que., at a cost of $10,000.

Aikenhead's

Grips the Entire Shank— Never Slips



Wahlstrom Chucks

The clutch of the Wahlstrom positively cannot slip. Its instant-acting jaws close on the entire shank with a grip that becomes firmer and firmer as the resistance to the tool increases.

There's no time lost in waste motion with the Wahlstrom Chuck. It is automatic and instantaneous in action. Two seconds is all you need to change from drilling to reaming, counterboring or tapping—and you don't stop the spindle.

In addition to regular drill press work they will increase production of lathes for burring, turning, filing, etc.

Made in two different styles. One style holds No. 1, 2, or 3 Morse Taper Shank Drills —with or without a tang. The other style is made in three sizes, which hold all sizes of straight shank tools from 1-4 to 1-inch.

The World's Standard of Accurate Gauging

Johansson

The "Limit System" introduced by a set of Johansson Gauges to your shop will assure equal results on all work, even in the hands of unskilled operators.

Johansson Gauges are the fulfillment of an ideal in measuring tools heretofore unattainable. They combine the advantages of both line and end measures. Like line measures they give all sizes within their range—like end measures they are convenient, solid, non-adjustable blocks of steel. They insure the same result any number of times and in the hands of any number of mechanics. This fact has made them indispensable where the work of one shop is to be assembled with the work of others.

No individual to-day is independent of the machine-shop. No machine-shop to-day can afford to be independent of Johansson gauges. They save time, decrease costs and increase both the quantity and quality of the work, factors of vital importance in these days of keen competition.

Mechanical Features of Motor Installation

Position of Motor Important—Question of Couplings—Gear Drives—Adjustment must be Arranged for—Belt Drives—Chain Drives—Speed of Chain Should Be Closely Watched.

By GORDON FOX*

IN selecting a motor for a given service, the location and method of drive should receive consideration. It is desirable to locate motors in cool, clean light, high, and dry places as far as possible. If the motor must necessarily be in a hot place, it must be liberally rated. If it must be in a dirty place, total or partial enclosure should be employed, for dirt causes many a failure. If moisture or fumes are present, the motor should be protected, as far as possible, and the insulation specially treated to meet the condition.

The position of a motor should be such that it is easily accessible for inspection, else neglect is probable. Clearance spaces should be provided for the removal of the entire motor or its parts. In the case of important machines, care should be exercised to see that part replacements may be quickly made. Failing this, the entire motor unit should be exchangeable. It is of advantage to have important moors served by a crane or repair trolley, or at least to provide ready means of rigging for handling of motors and parts.

Direct-connected motors are best mounted so as to be intrinsically a part of the driven machine. This is advisable for the sake of retaining alignment, but is not always necessary. Usually some form of bracket or platform is arranged. If it is not possible to attach this to finished surfaces, it may be bolted to the frame of the machine. The motor may be aligned and the bracket forced into position with wedges. A dam is then placed around the feet of the bracket and any spaces filled with lead.

Motors should not be supported or directly attached to machines which vibrate or shake, as the motors will likely develop trouble under such conditions. Railway, mine, and mill type motors are better adapted than general utility motors to withstand such conditions. In attaching a motor to a bedplate or similar support, through bolts are preferable to cap screws or stud bolts, as the motor may be more readily removed and breakage of a bolt is a less serious matter.

Care should be exercised to have the motor shaft level, otherwise end pounding may result.

When mounting motors upon a floor, it is best to use a base and to keep the motor above the dirt and moisture, with sufficient space for sweeping. A base is better than rails, especially where the floor is uneven, due to the tendency for rails to settle away from a plane surface. Motor bases should be heavy enough to retain shape under stress, but they should not be bolted down in a manner to distort them. Large motors may be neatly installed by providing a concrete foundation and anchor bolts, the motor base being aligned with wedges and grouted in. Motors without bases should not be routed in, as removal for exchange or repair is too difficult. If a base is not provided, heavy steel plates or rails may be grouted in the foundation, and anchor bolts passing up through the plates and also through the motor feet.

Side Wall Suspension.

Motors may be readily arranged for side-wall suspension by shifting the bearing brackets through 90°. They are sometimes attached to the ceiling for driving to the floor above. As the motor usually has a small pulley, it should be borne in mind that the weight of the belt decreases the tractive power. It is not the best practice to hang small direct-current motors directly from the ceiling, as they are inaccessible and do not receive proper attention. It is better to suspend the motor on some form of rack.

The structural supports for a motor should be sufficiently heavy and rigid to prevent movement and vibration. Use of channel-iron supports for wall or ceiling mounting is suggested as permitting easy alignment and rigidity.

Many motors are direct-connected to the driven machine, driving through couplings or gearing. Remote drives may be through belt, chain, or rope transmission. These various modes of application will be considered in sequence.

Couplings of both solid and flexible types are in common use for motor applications. Solid couplings are almost always of the safety flanged type. Flexible couplings supply a considerable measure of protection to the motor. They should be used where there is any possibility for relative movement of motor and machine, where there is vibration or shock in the driven machine, and where an end thrust occurs which might be imposed upon the motor.

Although the great majority of flexible coupling installations are successful, this type of coupling is necessarily less simple than the solid flanged coupling, and troubles are occasionally experienced. There are many designs of flexible coupling. The leather-link and leaber-buffer coupling are among the older ber-buffer couplign are among the older types. As both leather and rubber are subjected to deterioration, all-metal couplings have features of desirability. All-metal couplings are particularly well adapted for the more severe service applications, finding extensive use, for instance, in the steel mill.

Although flexible couplings permit of a small amount of relative motion, they should be aligned as perfectly as possible when installed. The margin then safeguards operation in case either part becomes slightly displaced. Limits of misalignment within which successful performance may be expected are about 1/16 in. offset of shaft centre lines and 5° angularity between shafts.

Gear Drives.

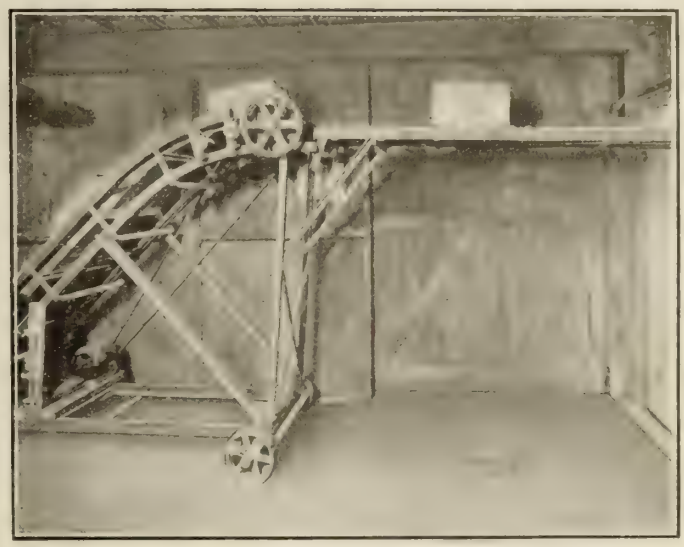
Gear drives permit of compact arrangement, are positive, and are particularly well adapted for slow-speed work. They have fair efficiency, ranging from 90% to 98%. They require good alignment, well maintained. They transmit all shocks to the motor. They are usually more or less noisy.

The ratio of the drive gearing depends upon the relation of motor speed under load and desired machine speed. In the case of constant or adjustable speed motors this ration is easily determined. In the case of variable-speed motors the proper ratio is not always so readily determined, as the motor speed varies with the load. For drives which start and stop frequently the factors of machine and motor inertia may materially affect the selection of gear ratio for the drive.

The allowable ratio for a single reduction is limited by the allowable diameter and surface speed of the gear and by the minimum number of pinion teeth. For small motors a 10-to-1 ratio is allowable. For moderate sizes 8-to-1 is about the maximum permissable. The motor pinion should have at least 15 teeth, if possible, as the teeth of smaller pinions are weakened by their undercut shape. In determining a ratio of gearing, it is well to avoid the maximum possible ratio, as this leaves no margin for future change, should such be found desirable. It is better to use an intermediate ratio, but to provide clearances which will permit of a change of the gear ratio in either direction, if desired later. In calculating a gear reduction the gear should, if possible, have a prime number of teeth, so that the shocks due to a repeated cycle of operation may be distributed; the use of an old tooth prevents the same teeth from meshing so often.

Can. Mach. July 7 Galley 14—

When motors have double-extended shafts, placing of the pinion on the commutator end should be avoided if possible, as the shocks and vibration are more severe and the bearing wear likely to be more rapid. Outboard bearings should be used for all geared motors of 100 R.P. and larger, and, in many cases, for smaller motors. Outboard bearings should be used for ordinary motors of 50 H.P. and above when subjected to reversing duty or severe fluctuating loads.



Permits of Adjustment.

The motor pinion should be located preferably on the same horizontal level and to one side of the driven gear. Bearing wear or slight errors in elevation then have little effect. It is not good practice to locate the motor pinion directly below the driven gear. Bearing wear is then likely to throw excess weight on to the motor bearings. It is also difficult to remove armatures so located. If the arrangement is such that motor elevation affects the meshing of the gearing (also for coupled drives), it is advisable to have the motor support a trifle low and to supply shims under the motor feet. This arrangement also permits of adjustment to care for differences in individual motors.

Gears are usually of cast iron or cast steel with cut teeth, while pinions may be of steel, brass, rawhide, fibre, or cloth. The latter types usually have end-plates of brass. Steel pinions have excellent life and are not affected by temperature or moisture, but are noisy and cut quickly unless well lubricated. Steel gears are about twice as strong as cast iron. They should be used for im-

MATHEWS GRAVITY CONVEYOR

Profit by the Experience of Others

WHEREVER you go in Canada today—a manufacturing plant, a cannery, a lumber mill, it really doesn't much matter—Mathews Gravity Carriers, Automatic Elevators, Belt Conveyors, Pallet and Flight Conveyors, and Chutes will be found quietly and efficiently doing their work.

Eliminate Unnecessary Labor

LABOR is one of the most costly items of modern shop operation. The cost of every bit of work which requires operations by more than one machine, is considerably higher than need be, if the piece must be trucked or carried by hand from one machine to another. Eliminate the labor expense and the cost is appreciably reduced.

Profit by the experience of others! Install Mathews Gravity Conveying System. If you haven't room on the floor, hang it from the ceiling up out of the way.

It will be worth your while to have our nearest sales engineer call at your convenience—without obligation, of course.

portant work, where shocks or overload may be expected, or where the face of a cast-iron gear would exceed 4½ in. The cost of cast-steel gears is about double that of cast iron gears. The pinion is subject to the more rapid wear, due to its smaller diameter, therefore it is important to have a pinion of good wearing qualities as well as of sufficient strength. Steel pinions are usually forged of 0.30% to 0.40% carbon steel, and are frequently heat-treated to increase their strength and durability.

Iron and steel gears ordinarily become noisy at about 800 ft. per min. linear speed, but may not be disagreeably noisy below 1,200 ft. per min., or even higher. Where it is desired to employ high surface speeds without noise, brass, fibre, rawhide, or cloth pinions may be used. Brass pinions, although somewhat quieter, have shorter life than steel. They are particularly adapted to conditions of heat and moisture prohibiting the use of a non-metal pinion. But where noise is objectionable, fibre pinions are quiet, but are not very rugged, and are subject to deterioration by moisture. Rawhide pinions are satisfactory unless subjected to extremes of heat or moisture or excessive load fluctuations, or frequent starting, stopping, or reversing. For equal strength, the face of rawhide pinions must be about 25% wider than corresponding steel pinions. The surface speed of a rawhide pinion is limited more by rapid wear than by noise. A speed of about 2,000 ft. per min. is a fair average limit, but 2,500 ft. to 3,000 ft. per. min. may be used under favorable circumstances of attendance and lubrication, in the absence of moisture, and for intermittent service where the life of the pinion is not important. Cloth pinions are quiet, not easily affected by heat or moisture, are quite elastic, and give good service when subjected to strains and shocks. The allowable surface speeds correspond to the values for rawhide. Where quiet operation is desired it should be noted that rigid and massive supports and close-fitting bearings, both on motor and driven machine, are conducive to a noiseless drive. The pinion should always be placed as close as possible to the motor bearing.

Gears must be kept well oiled, and at high speeds some method must be used the effectiveness of which will not be destroyed by centrifugal force. Rawhide gears should not be oiled, but should be lubricated with talcum and graphite or graphite and lard oil. Gears should always be guarded, both for safety and for protection and to prevent throwing of the lubricant. Inspection openings should be provided in the gear guards at the point of meshing.

Worm-gears are used for special cases where a large speed reduction is desired. They are positive, quiet, and free from vibration. They have low efficiencies, ranging from 70 to 80%, and require excellent machining and good lubrication. A carefully adjusted end-thrust bearing must also be provided. The worm should mesh with the bottom of the gear and should run in oil. If the worm is placed above the gear it will not receive good lubrication. The best rubbing-surface speed for worm-gears is about 300 ft. per min., although speeds as high as 700 ft. per min. are sometimes permissible. Worm-gears are not reversible—that is, the wheel will not drive the worm. They can sometimes be used in a braking capacity due to this feature.

Friction drives are useful where

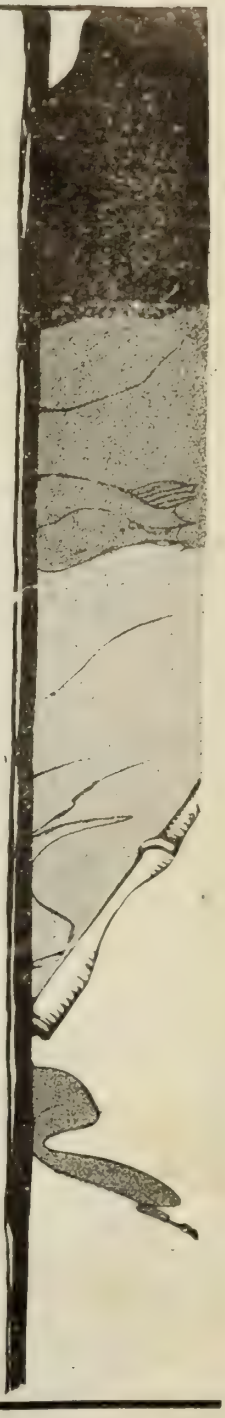
You Can't Row a Boat with One Oar

An unbalanced advertising campaign, like a one-oar boat, never gets anywhere.

Sound copy must be balanced by scientific space selection. Mediums deserve as much attention as merchandising.



To buy space scientifically circulation must be *analyzed*—not merely counted.

Do you ask of a publication not only "How much?" but also "How did you get it?" and "Where does it go?" If you fail in these particulars you are trying to make an advertising campaign go with only one oar.

The answers to these questions can be obtained by studying the A. B. C. reports. To read the circulation figures only is not enough, even though they are verified by the A. B. C. audit. This is but the beginning.

Advertising is being put to a test to-day, which it can meet if you put circulation to the test of A. B. C. reports.

Canadian Machinery is a member of The Audit Bureau of Circulations.

power is to be transmitted at high speed and low torque, for small amounts of power, and where it is desired to change the speed or throw into and out of gear while in motion.

Belt Drives.

Belt drives are simple, flexible, inexpensive, and elastic, affording protection to the motor in case of overloads and shocks. The drive occupies considerable space, however, is not so positive, has relatively high maintenance cost, and is not suited to rapid reversals or other than fairly uniform speed service.

In determining pulley sizes for a belt drive, the desired ratio and the belt speed are determining factors. The power which can be transmitted by a belt varies with the speed, increasing nearly in direct proportion until a linear speed of about 4,500 ft. per min. is reached. Beyond this, on account of increased centrifugal stresses, the effective transmitting power is reduced. Belt speeds between 2,000 ft. and 4,000 ft. per min. are conservative values. Ordinarily, about 1,000 ft. per min. is the minimum and 5,000 ft. per min. the maximum. It is most economical to operate belts within the range of conservative speeds, due to lower first cost and maintenance and minimum power loss. Where very low speeds are used, wide belts are required. The centre of the belt then overhangs the motor bearing some distance and trouble may ensue. Decrease of contact surface means higher belt stresses due to greater tension required to prevent slipping. Wherever possible, the lower side of the belt should be made the driving side, so that the sag may be at the top.

Single leather belts should, in general, be used for widths up to 6 in., and for use over pulleys less than 10 in. in diameter. Double leather belts should be used for most other installations, except the very large, when triple belts may be used. Rubber belts are elastic, durable even under adverse conditions of temperature and moisture, have good tensile strength, and are uniform in width and thickness; their tendency to stretch, however, is often a disadvantage. Laced belts should not be used for motor drives; endless belts are preferable. Belts should run with, and not against, the lap at the joint, and the joints should be smooth to prevent jarring. The grain side of the belt should run next to the pulley, because it is smoother and adheres more snugly; also because the flesh side is stronger and less liable to crack. A belt will transmit about 25% more power without slipping with the grain side next to the pulley.

Wobbling of belts is sometimes due to pulleys having unlike crowns. Flapping is usually caused by slippage between some portion of the belt and pulleys, resulting from grease spots on the belt. A back-and-forth movement of the belt at the pulley is caused by the edges of the belt being of unequal arrangement.

The distance between centres of the motor and driven shafts depends upon the relative elevation of the smaller pulbottom. The distance should be such as to allow a gentle sag. Five times the diameter of the larger pulley is usually a safe distance, provided the difference between the sizes of pulleys is not too great.

The maximum advisable ratios of reduction through a single set of pulleys are: 8 to 1 for motors about 5 H.P.; 6 to 1 for about 10 H.P.; 5 to 1 for 20 H.P.; and 4 to 1 for about 50 H.P. If it is desired to ascertain the smallest pulley under which the motor bearings will give service, this may be done by figuring the total belt tension required, according to the formulae given below.

For iron pulleys—

$$\text{Tension} = \frac{3 \times \text{H.P.} \times 33{,}000}{\text{belt travel, feet per minute}}$$

For wood pulleys—

$$\text{Tension} = \frac{2 \times \text{H.P.} \times 33{,}000}{\text{belt travel, feet per minute}}$$

Knowing the tension at the centre of the pulley, the distances between bearings and the overhang of the pulley centre, the shaft may be considered as a simple lever, and the thrust on the bearing next to the pulley determined. The thrust per unit of projected bearing area may then be figured if the bearing dimensions are known. For motors under 50 H.P. the pressure per square inch bearing area should not exceed 70 lbs. For large motors, pressures up to 100 lbs. are allowable under favorable circumstances. Since belt tension must increase rapidly with a decrease in diameter, the limitations imposed by the bearings are usually the factors determining minimum diameter and maximum face.

Where there is insufficient space between the pulley centres to permit an open belt, or where the ratio of speed reduction desired is too great for open belting, or where a compact drive is desired, a belt tightening device on the motor is warranted. As it affords good arcs of contact, low tensions may be used and there is little or no loss in efficiency. The ability of the belt tightener to decrease slippage and to lower maintenance expense, as well as to increase reliability should recommend its use in many cases.

Large pulleys and those running at fairly high speeds should be carefully balanced by placing them on a mandril and balancing them on ways. It is well to use gib keys for pulleys, also for pinions, to facilitate removal. Series motors should never be belted, as the belt is liable to slip off, relieving the motor of its load and permitting it to race.

Chain Drive.

The silent chain drive is excellent for many applications. It is quiet and efficient, and permits of compact layout. Moreover it can be used for wide reduction ratios, particularly where the motor cannot be placed close enough for gearing. The centre line distance for silent chain drives should approximately be equal to one half the combined sprocket diameter, plus half the diameter of the larger sprocket. In a vertical drive the small wheel should not, if possible, be the upper one. Where feasible it is best to have the pull on the bottom of the chain. To provide for elongation particularly in vertical drives where the chain tends to fall away from the lower sprocket a sliding base should be used. The driven wheel should be flanged. Where the load is of a pulsating character it is well to use a driven sprocket with a spring centre to absorb fluctuations. Chains and wheel should be protected from dirt. When operating at speeds above 1,300 feet per minute they throw off their lubricant. Therefore should be enclosed and run in oil. The best practice restricts the chain to not over 1,000 feet per minute travel.

BANKS ASSIST EXPORTS

Continued from page 82

we could not at least try to do. One thing we have always stressed—and I think you will agree with me that we are right—is that an attempt to commence business by correspondence is a difficult and perhaps an unsatisfactory thing. I know that it is sometimes necessary, and that everyone cannot afford to take a trip to a prospective market. Where they can, it is by far the best way, and Canadian business men who go abroad will find that Canadian bank branches, or Canadian bank correspondents, are there to assist them wherever they go. I think that these service departments of our banks have really been of service. I know one of them at any rate that has passed a great many thousand dollars' worth of orders on to Canadian manufacturers who have filled them, and—what's more—have received cash for them. Such departments have during the last year or two had a peculiar situation to deal with. Until about a year ago, it was foreign importers who were writing us, asking for the names of sellers, and Canadian firms who were themselves too busy to accept new business. Now, when more goods are available, foreign conditions are not what they were. In spite of that, however, business is done.

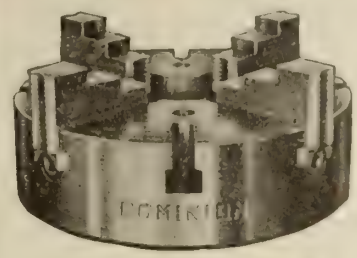
TRADE GOSSIP.

Savard Motor Sales, 124 Laurier Ave., Montreal, are contemplating the erection of a garage.

The Municipal Council, Bagotville, Que., are contemplating the construction of a Hydro-electric plant.

Jos. Langevin, Coteau du Lac, Que., is contemplating the erection of power house and electric line at cost of $20,000.

The Dominion Power and Transmission Co., Terminal Station, Hamilton, Ont., contemplates laying new street railway tracks on York St.



John Inglis Co., Ltd., 14 Strachan Ave., Toronto, have been awarded the contract for 7 150 H.P. Boilers by the Canadian Oil Companies, Excelsior Life Bldg., Toronto.

Reid and Brown Structural Steel and Iron Works, Ltd., 63 Esplanade E., Toronto have received the steel contract for garage costing $10,000, for J. M. Schneider and Son, 53 Courtland Ave., Kitchener, Ont.

A reader of Canadian Machinery desires particulars of new or second hand light machinery suitable for cabinet work. Those who feel they can supply this information should write J. Talbot, Ridgeway, Ont.

CEMENT FORMULA.

A formula that is said to give very satisfactory results for water-proofing cement is a solution of lye and alum. Five pounds of powdered alum and 1 lb. of lye are dissolved in 10 quarts of water. Use ½ pint of this solution to each bucketful of water used in mixing the cement. For outside waterproofing add ½ pint of this mixture to a bucket of water, and thicken with pure cement to the consistency of a heavy wash.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

MACHINERY FOR SALE

Lathes

1—24" Rockford Shaper, back geared
1—26" Back geared Drill, lever feed only
1—No. 54 Perkin Spring Cutter
1—No. 320 Brown-Boggs Press
1—10"x24" Plain Landis Grinder, self-contained
1—Union Triplex Hydraulic Pump, 1½ x 1"
1—26" x 12' Pond Lathe, S.B.G., C.R., P.C.F.
1—24" x 12' New Haven Lathe, D.B.G., S-Q.C.G., C.R.
1—24" x 12' Can. Mach. Lathe, S.B.G., C.R., P.C.F.
2—22" x 10' Davis Lathes, D.B.G., Q.C.G., C.R.
1—21" x 10' London Lathe, S.B.G., C.R., P.C.F.
4—20" x 8' C.M.C. Lathes, D.B.G., S-Q.C.G., C.R.
3—18" x 8' C.M.C. Lathes, D.B.G., Q.C.G., C.R.
1—20" x 10' Butler Lathe, D.B.G., Q.C.G., C.R.
1—16" x 6' McDougall Lathe, S.B.G., S-Q.C.G., C.R.
1—18" x 8' Mueller Lathe, D.B.G., Q.C.G. Turret on cross slide.

Shapers

1—24" Rockford Shaper.
1—12" Port Hope Shaper.

Drills

1—No. D-1 H.D. Colburn Drill.
2—No 24 H.D. Foote Burt Drills.
1—28" Barnes Drill, B.G., P.F.
1—22" Barnes Drill, B.G., P.F.
1—20" McDougall Drills, W. & L.F.

Miscellaneous

2—2" x 26" Pratt & Whitney Turrets.
1—No. 2 Gardner Disc Grinder.
1—3" Acme Bolt Cutter.

YEATES MACHINERY

HALE STREET
LONDON, ONT.

GARLOCK-WALKER LIST

Over 20,000 square feet in our warehouse is filled with every variety of Equipment for Machine Shops and Woodworking Factories.

You will find Garlock-Walker service thoroughly dependable. Let us know what Machinery you require.

If you want Machinery Equipment, send us your enquiries.

A few Machines from our Toronto stock at exceptionally attractive prices are:—

LATHES

1—144" x 12' Berg Pit Lathe (used).
1—36" x 18' Putnam (used).
1—30" x 12' Blaisdell (used).
1—30" x 14' Niles-Bement-Pond (used).
1—26" x 14' Niles-Bement-Pond (used).
1—24" x 10' Milwaukee (new).
1—20" x 6' Le Blond Heavy Production (used).
1—18" x 8' Bertram (rebuilt).
1—18" x 8' Rae (new).
1—16" x 6' Reed (used).
1—12" x 8' LeBlond (used).
1—8" Rivett, Bench, Cabinet and Attachments (used).
1—7" Cataract Precision, Standard Equipment.

GAP LATHES

1—22" x 40" x 16' McDougall (used).
1—20" x 38" x 12' C. M. C. (used).
1—18" x 24" x 10' Rahn Meyer (used).

TURRET LATHES & SCREW MACHINES

Several No. 4 Millhollands, Davis, Oliver, Garvin, Warner & Swasey, and National Acme.

SHAPERS

1—16" Rae B. G. Crank Shaper (new).
1—24" McGregor-Gourlay Crank Shaper (used).

PLANERS

1—42" x 42" x 20' Putnam, 1 Head (used).
1—48" x 48" x 14' Patch, 4 Heads.
1—36" x 36" x 24' Sellers, Open Side (3 Heads).
1—30" x 30" x 10' Pond, 1 Head.

MILLING MACHINES

1—Briggs High Duty Type "A", 22" Traverse (new).
1—Briggs High Duty Type "B" 42" Traverse (new).
1—Ryerson-Owen No. 3, Universal (new).
1—Ford-Smith, No. 3 Universal (used).
Several Plain and Small Hand Millers.

DRILLS

1—10" Burke Sensitive Bench (new).
1—15" Rockford (used).
1—16" No. 2B Edlund H. S. Sensitive (new).
20" "Sibley," "Champions," "Rockwell" and "Silver" (new and used).

BORING MILLS

1—Universal No. 2½ Horizontal, Table 42" x 22" (used).
1—Bullard "New Era" Type Vertical Turret, 36", Complete Equipment (new).

POWER HACK SAWS

1—No. 10 Racine 8" x 8" Cap. (new).
1—No. 7 Watkins, 9" Cap. (used).
1—No. 1 Racine, 6" x 6" Cap. (used).

GRINDING MACHINES

1—Landis No. 4 Universal (used).
1—Landis Plain, self-contained, 36" x 12" (used).
1—Fitchburg Cylindrical, 8" x 36" (new).
Tool and Cutter Grinders. New and used. "Globe," Stevens, LeBlond and Cincinnati.

AIR COMPRESSORS

1—8" x 8" Sullivan, Class W.G.-3, belt driven (used).
1—8" x 10" x 8" Bury, steam driven (used).
1—12" x 18" Ingersoll-Sargent, belt drive (used).
1—12" x 12" Can. Ingersoll-Rand, N.-E.-1 (used).

PRESSES

1—No. 0 Consolidated Inclinable Power Press (used).

MISCELLANEOUS

2—No. 4 Jno. Hall Pipe Machines (1 used), (1 new).
1—No. 4 Jno. Hall Nipple Machine (used).
1—Lennox Rotary Bevel Shear, 1" cap. (new).
1—6" Curtis Pipe Machine (used).
1—Beaudry Champion Power Hammer, No. 9 (used).
1—Grant Rivet Spinning Machine, No. 80A (new).
1—Grant Rivet Spinning Machine, No. 80B (used).
1—Greenerd Arbor Press No. 4 (used).
Transmission Equipment, Pulleys, Belting, Shafting and Hangers.

TRADE K—T MARK
FOUNDRY
GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. **Ask us.**

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

INTERNATIONAL MALLEABLE IRON CO., LIMITED
GUELPH, ONTARIO, CANADA

Malleable and Cast Iron PIPE FITTINGS

Made in Canada and Exported Abroad

A LARGE plant, up-to-date facilities and thoroughly experienced staff place us in a position to offer unequalled quality, price and quick delivery on Malleable and Cast Iron Pipe Fittings; both screwed or flanged, black or galvanized. All sizes from ⅛ inch up.

We make a specialty of exporting our products and can furnish designs required in any country, such as the Whitworth or "V" thread in use in England, the Metric Pitch in France, or the W. S. Standard in use in Canada and United States.

We will be glad to answer your enquiries.

International Malleable Iron Co.
Limited
GUELPH, ONTARIO, CANADA

"Easy as Throwing a Gear Out of Mesh"

Just a slight movement of the operator's thumb and the NAMCO Collapsing Tap shown below is ready to thread another of the cylinders.

Simple, isn't it? And yet how much simpler is the automatic action that positively collapses these tools when the required depth is required.

The collapsing or re-setting action is positive and as simple as throwing a gear out of mesh. This means minimum shortage of work, rapid output and low per piece cost.

You can't help noticing the good qualities of

Pratt & Whitney Taps

Their free cutting qualities, their extreme accuracy and their extraordinary ability to outlive others distinguish them.

The con-eccentric relief—a distinctive P & W feature—is the secret of their goodness. One-third of the cutting edge is concentric. The remaining two-thirds has eccentric relief. Taps can be sharpened at the only correct point—on the face of the cutting edge. Sharpening in no way effects their size.

Yes, they cost a little more than some others, but they're well worth the difference. Carried in stock as are all other P & W Small Tools at our sales offices and agencies as listed.

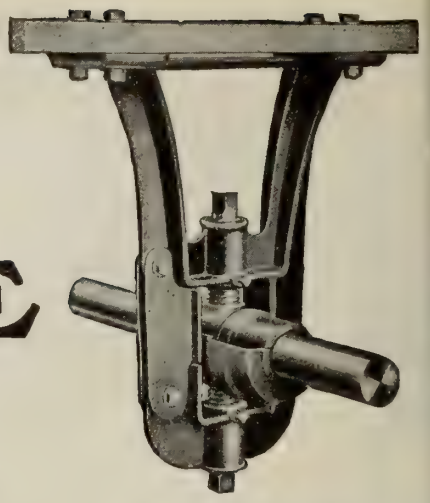
DODGE

Steel Shaft Hanger

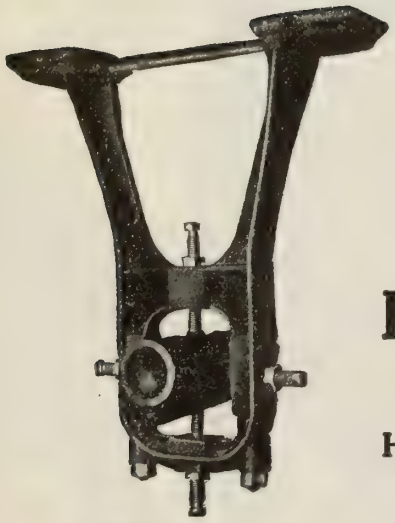
DODGE



Hangers for line shaft service

Dodge Hanger users everywhere have learned that they can safely use whatever type of hangers they choose, as long as it is Dodge-built.

Dodge Hangers are the best obtainable everywhere in any type or size; specify them for line shaft service under any conditions.



Dodge will at any time give an unbiased opinion concerning the right hanger type for any job—an opinion based on and backed by the best engineering knowledge and practice.

But whether that opinion is accepted or disregarded for personal preference, the final selection should in every case be Dodge.

Have You Any MACHINERY PROBLEMS?

Our Engineering Staff is at Your Service

OUR Engineering staff understand Canadian Manufacturing conditions thoroughly. Why not put your problems up to them? They are prepared to give you the benefit of their wide and varied experience without obligation. Their advice has been of practical value to others and no doubt they can serve you just as well.

When you need anything in Machinery and Supplies remember that we can supply your needs with new or used equipment. There is nothing we cannot furnish in new equipment from our immense stocks—and we also have a lot of good used tools on hand which you should investigate; they are being sold at very attractive prices.

The Coventry Patent Self-Opening Diehead

MADE IN SEVEN SIZES—5/16", ½", ¾", 1", 1¼", 2" and 3"

THE Coventry Diehead produces clean smooth threads, accurate in form and pitch. The Coventry chaser grinding system ensures exceptional life to the chasers and the greatest ease in grinding; all chasers are ground together on any type of surface grinder.

THE purchase of a diehead involves the important question of prompt service on chasers. We offer very thorough service in this respect.

We Carry in Toronto Stock

Chasers With
U.S. Standard Thread
Briggs Pipe Thread
A.S.M.E. Thread
S.A.E. Thread
Whitworth Thread

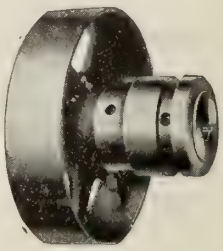
THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30x5 driven from one line shaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operaton at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY.

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST.

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet "Clutches As Applied to Machine Building." and our Yellow Catalog.

KEMPSMITH

No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-story frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request

HESPELER, ONTARIO

The New Canadian-Detroit Double-D Rolled Drill

Made in Canada

PRODUCTION requirements in an ever-increasing number of plants necessitate the use of a strong, accurate drill, specially designed for hard drop forgings, steel castings, and other alloy steels equally tough and difficult to drill.

For this service we have developed a hot rolled process drill known as the Canadian-Detroit Double-D (DD) Rolled Drill. It combines the strength of the forged type drill with the accuracy and uniformity of the milled type.

The flute of the DD is formed straight from the bar stock by successive passes through specially built and patented rolls at a temperature of 1850° F. This mechanical rolling of the flutes produces a refinement and uniformity in the grain of the steel and gives additional density at the centre and at the outer edge. Each drill is rolled separately, and the rolls are so designed and operated as to produce the same uniform increase in web thickness as is obtained in high-grade drill of the milled type.

The fluted drill is reheated and twisted in a specially designed automatic machine. The twisting process is held absolutely uniform, giving the same increase in helix angle from shank to point, 27° to 32°. This standard has been adopted on our milled drills and has been proven by exhaustive experiments to be the most efficient.

The DD has increased production and cut drilling costs in many of the finest plants in Canada. A fair test will convince you.

Manufactured and carried in stock at Walkerville in all sizes from ½ inch to 1½ inches.

We also manufacture and carry in stock all sizes and types of high speed and carbon milled drills.

"Show me a man whose kit contains a complete outfit of Starrett Tools and ten to one he's either a mighty good machinist, or the makings of one.

"In the first place he knows tools. That's why he bought Starrett's. Or even if he bought 'em on the say-so of someone else, I'll take my hat off to him as a man whose got sense enough to take good advice.

"And, secondly, it shows that he knows the value of always having the proper tool for any job right in his own kit.

"Many a foreman will not hire a man who hasn't a good tool outfit.

"If a machinist borrows tools it wastes time, and is apt to make trouble.

"If he tries to get along without—and make such tools as he has do for the work on which other tools save time and are more accurate—it means more lost time and more spoilage.

"Starrett Tools are the machinist's best friends. And the more of these friends he has on the job, the better the job will go.

"Ask the hardware man to show you the full Starrett line.

"And—first of all—write for the Starrett Catalog No. 22 -3"

Valvular Tank Trouble

WHEN oxygen tank valves leak—in transit or in operation—dollars are dissipated in the air instead of being pocketed by efficient welding or cutting work at the blowpipe tip.

Dominion Oxygen cylinders—like the product—are perfected in every detail. The Wedge Valve on a Dominion Oxygen tank cannot leak. It is the evolution of years of painstaking study, both in design and structural material.

Forged from bar stock, it resists the wear and tear of internal friction and if foreign matter, by any chance, score the face the valve re-seats itself while the tank is fully charged and in operation — a unique time and money-saving feature. And a twist of the fingers is all that is necessary. No tools are required.

This insurance against interruptions and failures has commended itself to all users of Dominion Oxygen. It also means that Dominion Oxygen reaches the consumer free from impurities and with cylinders filled to capacity—there can be no leakage en route or in application.

And with six centrally located distributing stations in full operation, the Dominion Oxygen Company, Limited, is prepared to supply consumers with any quantity of uniformly pure oxygen anywhere. Our policy of filling all orders on the day of receipt means the quickest and most satisfying oxygen service in the Dominion.

Goulds Triplex Pumps Reduce Pumping Costs

Vast numbers of Goulds Pumps are working perfectly day and night, in thousands of plants, great and small. There is no doubt as to their successful performance. They are the Leaders in reliability and operating efficiency. May be driven by any motive power. They will show a saving of two-thirds and more in pumping costs over directacting steam pumps of the same capacities and pressures.

Poole Turbo-Gear Has an Efficiency of Over 98 per cent

The Turbo-Gear is a mechanical step-up or step-down speed transforming device. It is coupled between and directly to the prime mover and the driven unit. Turbo-Gear is pure torque transmission. There is no side strain on shafts or bearings. Forced lubrication, economy of space and maintenance, and absolutely quiet running are some of the other factors behind its 98% efficiency—plus.

VOL. XXVI. No. 2. July 14, 1921

The Pyrometer As An Aid To Heart Treatment

The Pyrometer is Now Thoroughly Practical for Everyday Shop Use—Different Temperatures Can Be Handled Easily—Recording Type Becoming More Popular—Description of Its Action—Method of Installing

FOR indicating or recording temperatures higher than 800° F., Thermo-Electric pyrometers are extensively used. The "Thermo-Electric" principle as applied to pyrometry, was first discovered in 1820 by Seebeck and has been developed so that the pyrometer instrument is now thoroughly practical for everyday shop use. When two wires of dissimilar metals or alloys (called thermo-couple) are heated at the point of junction, an electrical current is generated—this phenomenon is known as the "Thermo-Electric" principle. The current generated is measured by an electrical instrument known as a Millivoltmeter, the scale of which is graduated in degrees of temperature and the equipment constitutes the modern Thermo-Electric pyrometer.

For temperatures above 2,000° F., a thermo-couple of Platinum—Platinum-Rhodium is used. This consists of one element of platinum and the other of platinum and 10 per cent. rhodium. This combination will generate a potential of about 17-millivolts, and is used for taking readings as high as 3,000° F. Because of the delicacy and care required in handling the platinum couple together with the first high cost, for temperatures below 2,000° F., a thermo-couple of base metals or alloys is more commonly used. These base metal couples are not as fragile, and less expensive. There are a great many applications for which pyrometers may be used in the machine shop. Some of the more important ones come under the classification of "Heat Treatment of Steel," including tempering, hardening, annealing, etc.

In some classes of work in connection with small furnaces, an Indicating Pyrometer as shown in Fig. 1, is sufficient to guide the operator. However, for larger furnaces and for work where long periods of heat treatment are required, a Recording Pyrometer like Fig. 2 gives better results and a complete check on the accuracy of the work is supplied with the chart record made. One pyrometer instrument may be connected by switches to any number of thermo-couples, so that readings may be taken in several different furnaces without changing leads and thermo-couples. A combination of indicating and recording instruments are very often used. The indicator near the furnace to guide the operator and the recorder in the office where a constant check on the work in hand may be had.

Recording Pyrometer.

The recording pyrometer, however, is becoming more and more popular for use by the operator, because it not only provides an indication of the temperatures, but also records the temperature over a period of time, making it possible to keep a check on what actually takes place. It shows what the temperatures are now, what they have been, and in what direction they are leading. This is especially important where the process involves the time element. In fact the recorder tells the complete temperature story.

When selecting a pyrometer it is advisable to give the manufacturer of the equipment a complete outline of requirements; including the character and material to be treated and the usual temperatures required to cover. Also the length of leads necessary between the thermo-couple and the instrument. A very important feature is the protection well used to protect the thermo-couple. This should be considered both from the standpoint of possible mechanical injury and chemical action due to fumes and gases to which it may be exposed, in order to obtain the maximum service from the thermo-couple.

Until recently the one big hindrance to thermo-electric pyrometry was the method required to maintain a constant cold-end. Several devices are used which partially take care of the cold-end error, but some of these are very

Illustrations and data through courtesy of the Bristol Co., Waterbury, Conn.

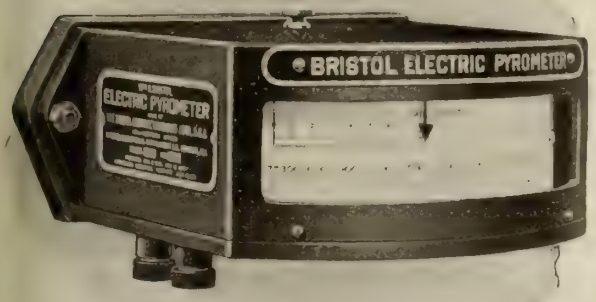

FIG. 1—AN INDICATING PYROMETER.

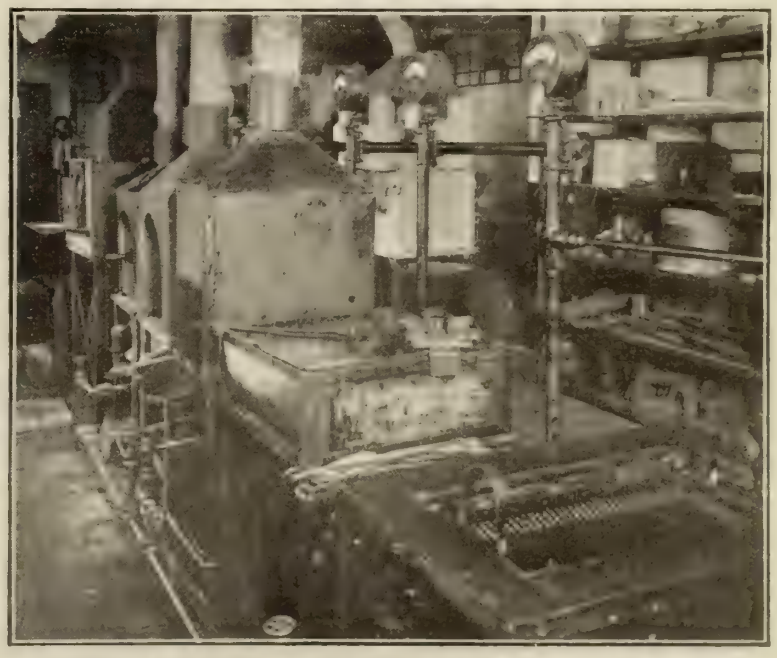

FIG. 4—SHOWING A RATHER NEAT INSTALLATION.

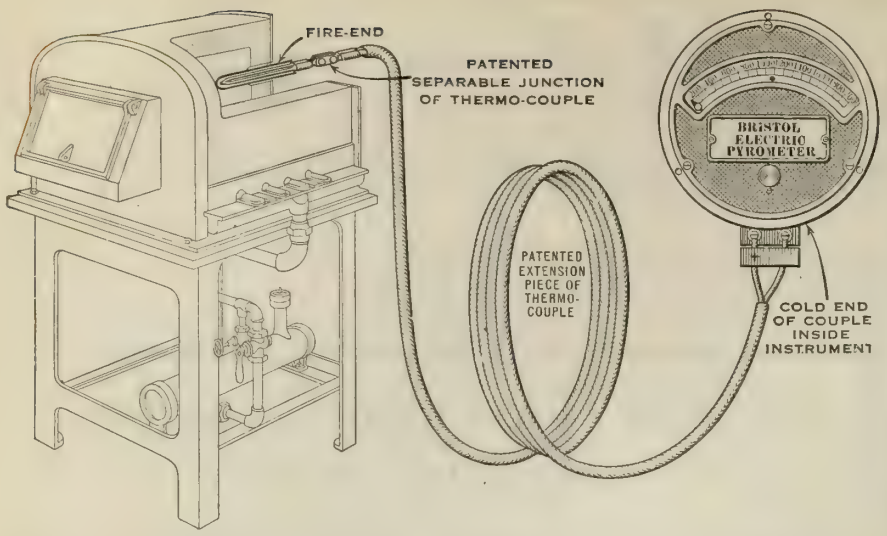

FIG. 3—ONE METHOD OF APPLYNG PYROMETER TO SMALL GAS FURNACE.

FIG. 2—A RECORDING PYROMETER.

expensive and also impracticable because cumbersome and complicated. A recent development in cold-end compensation is the automatic internal cold-end compensator. This is a very simple device installed in the pyrometer instrument itself.

When the compensator is used the flexible extension lead is made of the same elements as the thermo-couple. This makes the instrument the cold-end of the thermo-couple, and as the device automatically compensates for any variations in temperature it obviates any necessity for maintaining constant cold-end. This method of automatic cold-end compensation eliminates all the complicated wiring and equipment formerly necessary, and, furthermore the readings on the pyrometer are absolute. The complete pyrometer outfit is simplified and now consists of three parts only—the thermo-couple, flexible extension lead, and the instrument.

Figure 3 shows one method of applying a pyrometer to a small gas furnace. Attention is especially directed to the simplicity of the pyrometer equipment, consisting of the thermo-couple in the furnace, the flexible extension lead and the instrument itself. This clearly illustrates the simplicity possible where the compensation is applied.

Recording pyrometers are often used in connection with electric furnaces which are used to temper steel parts for automobiles, these operating at temperatures between 1,290° and 1,350° F. The furnace temperatures are usually controlled by a pyrometer regulator and the recorder gives the foreman a check on the accuracy of the regulator.

The pyrometers of the indicating type shown in Figure 4 are used in connection with hardening and annealing. The instruments are mounted directly back of the furnaces on standards. The flexible lead to the thermo-couple is enclosed in the pipe.

Several other installations in photographic form are at present before us, these including equipment for a hardening and annealing furnace; for pack hardening furnaces; also equipment for asphalt stills. To state the uses of pyrometers in a short article of this nature is impossible, but enough has been said to emphasize the importance of pyrometers in obtaining accurate results in any phase of heat treatment.

BEVELING TO PROVIDE FOR CONTRACTION.

When setting a patch in a firebox sheet and welding with the oxy-acetylene torch it is necessary to provide for expansion and contraction. It is customary in some railway shops to bump or corrugate the patch so as to provide a certain amount of elasticity within the sheet itself. Another method is turning the sharp edges of the bevels back with a fuller tool. The practice is substantially as follows:

The defective portion of the side sheet is cut out and beveled to an angle of about 45 degrees. The corners of the openings are rounded to a radius of about one inch or thereabouts. The patch is cut to the same dimensions as the opening and beveled all around to an angle of 45 degrees. It is drilled and tapped for the staybolts set in place and the staybolts screwed in. The edges of the plates are heated with the torch and a fuller tool from 3/16-inch to ¼-inch wide is driven into the vee to curl the sharp edges back. This is done all around before starting to weld. Welding is started at one corner, using filler rod to bridge the opening, and the "tack" is carried clear around without stopping. Welding then is done in the usual manner, using the torch and the welding rod in approved fashion to puddle and make a ripple weld.

No reinforcement is required; i.e., it is not necessary to build the weld above the level of the sheet. The curled edges tack welded are put in tension but they are supposed to yield by straightening out. When welding has been completed the projection of the curled edges on the far side of the plate should be reduced to a negligible amount.

Unfortunately, the practice just described to provide for expansion and contraction, is not preferable to bumping or corrugating the patch, because the elasticity of the curved edges is more apparent than real.

DETERMINING STRENGTH.

An electrolytic method of determining the strength of certain kinds of solutions, which can be applied to analysis of steels, is described in L'Industrie Electrique. Two electrodes, one of platinum and the other of calomel, are used. The former is immersed in the liquid to be tested, and the latter is in a separate vessel containing a neutral solution connected by a syphon to the main electrolyte, which is an oxidizing solution. The electro-motive force produced is watched by means of a galvanometer, and a neutralizing solution is added to the electrolyte drop by drop until the voltage suddenly falls off. The strength of the original solution can then be determined from the amount of neutralizer added.

BENDING WITH THE AID OF THE TORCH.

Repair men using welding torches soon learn to apply them when bending and straightening shafts, bars and structural parts. A workman who understands heating in just the right spots can quickly straighten a badly bent piece with the expenditure of very little gas and strength.

A secret of easy bending, continues Autogenous Welding, is heating a small area to a bright red or yellow heat and bending no more than necessary. Several heats may be necessary, each followed by angular displacement which in the total restores the part to the original lines.

Heating in a forge fire is at a disadvantage or bending and straightening, often-times because of the impossibility of confining the heat to a small section. Hence, the bend cannot be exactly localized where wanted.

A skilled straightener using the oxy-acetylene torch can bend his work with very little or no hammering, a matter of great importance when working on finished pieces. When bending structural steel it will be necessary often to cut flanges and remove parts to allow the bends to be made without distortion. The cutting torch is a most convenient tool for the purpose, of course. In fact, wonders can be accomplished by a welder and helper, using a cast iron floor plate to anchor and align, a welding torch to heat and a cutting torch to vee out for bending. The cuts can be so made that the flanges are readily welded again after bending, thus producing fabricated parts of any shape, still having the strength and characteristics of the original section before bending.

What is a Comprehensive Purchasing System?

In Organizing an Effective Purchasing System Three Things Must be Kept in Mind; First—Experienced Buyers—Second—One Man Must Direct Operations—Third—A Definite System Must be Adopted.

By WILFRED G. ASBLE.

RIGHT buying—of materials, to be shaped into products; of goods to be sold again; of equipment, to handle manufacturing; of supplies, to satisfy the daily wants of the factory—is one of the most important steps in distribution. To keep the wheels of the modern business in motion the price paid must be judged only in relation to the value secured. Each purchasing agent's effort towards helping the big national industries counts in the profits of all.

In organizing an effective purchasing department three things must be given the most careful consideration. First, a staff of able, experienced buyers must be secured; second, there must be one man at the top to coordinate, unify, and direct in a general way the work of these buyers; and third, there must be a system which will get the best prices, the quickest shipments, and an absolutely accurate knowledge in regard to stock on hand.

To handle the many details of a purchasing department with the accuracy necessary in such work requires a definite, coherent plan of recording, filing, and ordering. No slipshod methods will do, for prices must be definitely kept in mind and deliveries hurried in on the desired date. The system used must be essentially practicable and built around your business. It is folly to try and fit your business to any set system.

Sources of Supply.

In compiling and tabulating information regarding sources of supply there are several factors to be taken into consideration. Firms to whom business is given, and those with whom negotiations are conducted, should not only be able to make the goods, but should be so geographically located that you will have an unfailing source of supply.

Information as to sources of supply can be obtained from at least three different sources. First, through trade journals (supply, consumption and prices), which are clipped and filed. Second, through a catalog file. There are many ways of filing catalogs, but the most simple way is to number them and file them numerically in a correspondence unit. A card index should then be maintained in connection with this file. One set filed by name of manufacturer, as illustrated in Figure 1, and the other filed by article, as illustrated in Figure 2, while the third source of securing buying information is through a buyer's directory.

Purchasing Agent

FIG. 5—SHOWING CIRCULAR FORM OF LETTER.

Quotations and Prices.

When a requisition is received for an article not carried in stock, or when the supply of a particular item has reached the minimum, a quotation sheet, illustrated at Figure 3, is sent to the concerns handling the desired article. This form asks for a quotation by a specific date, the terms and number of days from receipt of order necessary to make shipment. These forms are sent out in duplicate, and after a firm has filled in the necessary information one copy of the sheet is returned to the purchasing agent.

Promiscuous requests to manufacturers for quotations will work to the disadvantage of the purchaser. The real buyer is the man who can discover live prospects among those concerns who are able to sell him what he wants, when he wants it, and at the right price. To be able to do this the purchasing agent must, by a process of selection and elimination make his list of suppliers accurate, complete and confined to those concerns which are in the best position to supply his requirements.

Quotation Record Card.

As the quotation sheets come in, the data is entered on a quotation record card, illustrated as Figure 4. This permits a quick survey for the purpose of choosing the company with which to place the order. These cards are filed by material and are referred to when making later purchases. After calling for a number of quotations on an article, and after the order has been placed and acknowledged, those concerns who furnished quotations should be notified that the order has been placed elsewhere. As a matter of courtesy this is due them. Such notification can be in the form of a postal card or by letter. It is my opinion that a letter is the best form. This can be in circular form, printed as illustrated in Figure 5.

The Purchase Order.

Figure 6 shows the purchase order form. All forms are stamped with a serial number and are bound in alternating sheets of white, green, pink, and yellow. There is at present no standard form for the purchase order. Take a dozen different orders coming into an office and you will find that rarely no two are alike in wording, though in size a standard is often observed, that of 8½ x 11½—letter size. The odd size purchase order sheet is a bother in a systematic office, but the National Association of Purchasing Agents have made a move for more uniform stationery.

The first or white sheet goes to the

supplier. The second or green copy is the acknowledgment form and goes to the supplier, after which it is filled in and returned to the purchasing agent. The third or pink copy goes into the purchasing agent's follow-up file. Ordinarily the fourth, or yellow copy, goes to the receiving room to assist the receiving clerk in checking up receipts. This procedure, however, is now condemned .

Receiving Methods.

The receiving clerk if obliged to check only the number or quantity of goods will not be as particular as though that column were left blank and he had to fill it in on arrival of the shipment. This would necessitate an accurate count and instead of being just a check mark it would be written in the handwriting of the receiving clerk. In order to effect this a slip of paper the width of the quantity column is tipped to the fourth or yellow sheet of the purchase order. This slip takes the carbon impression of the quantity column and is removed and discarded, leaving the blank with that information to be supplied. This method prevents any careless checking on the part of the receiving clerk.

If the receiving clerk is under the jurisdiction of the storekeeper, the fourth or yellow copy may go to the storekeeper with the rider attached. He thereupon removes the rider, numbering the back to correspond with the order number, when he turns over the form to the receiving clerk to check. This enables the storekeeper to have any discrepancies checked immediately. This method does away with a memorandum of receipt blank sometimes used. The fourth or yellow copy of the purchase order properly checked is used in its place.

FIG. 9—PEPETUAL INVENTORY RECORD CARD.

Acknowledgment of Order.

The acknowledgment form, illustrated at Figure 7, is enclosed with each order. This takes the place of a return letter of acknowledgment and often accelerates delivery by binding the supplier to do a definite thing—a good plan at all times. When this form is received a signal is placed over the date on the follow-up folder in which the third or pink copy of the purchase order has been placed, showing when goods are expected to be shipped.

Purchase Record Card.

When making purchases, it is often desirable to have, for reference, a record of former purchases of the same material. A purchase record card, il-

FIG. 3—SHOWING STYLE OF QUOTATION SHEET USED.

lustrated at Figure 8, is used for this purpose. Such a record, properly kept up-to-date, acts as a supplement to the quotation record. Further, there are times when an article is needed in a hurry with no time to secure prices. This record will then enable the rush order to be placed intelligently and with a considerable degree of certainty that a fair deal will be given you.

Perpetual Inventory Record.

The perpetual inventory record card, illustrated at Figure 9, shows at a glance the maximum and minimum supply of any article. This record has been the subject of much study, both as to the devising of proper forms and in their use to determine accurately the amount of material or supplies on hand at any given time. The working of this record is extremely simple, only requiring that the accurate report of all incoming and outgoing stock be recorded and the balances brought forward. Thus, when the balance on hand shows that the minimum has been reached, attention is automatically brought to this fact.

The up-to-date modern purchasing agent should be a man of good education, a big broad-minded, broad-gauged fellow, with big ideas, strength of character sufficient to withstand temptations to petty or great graft, and with a vision of things which compels a system in all he does. He should keep himself posted on general conditions of business, being alive to what is going on in the various markets, and keep especially properly posted on lines he handles. To this end, he should be a reading man—a reader of such trade periodicals as are devoted to his and related lines.

He should be self-contained, self-possessed, and a quiet man. This makes him strong in his place. As someone has said, "Power is usually the quietest thing in the world. As a rule it makes the fewest motions and the least noise. It never spends itself in ways that count for nothing. When we are in the presence of men and women of real power we are in the presence of peace and quiet. Such a presence is conducive to confidence, and a mighty helper to fair and honest decisions. A man of power knows that the smallest things can destroy the power of the strongest."

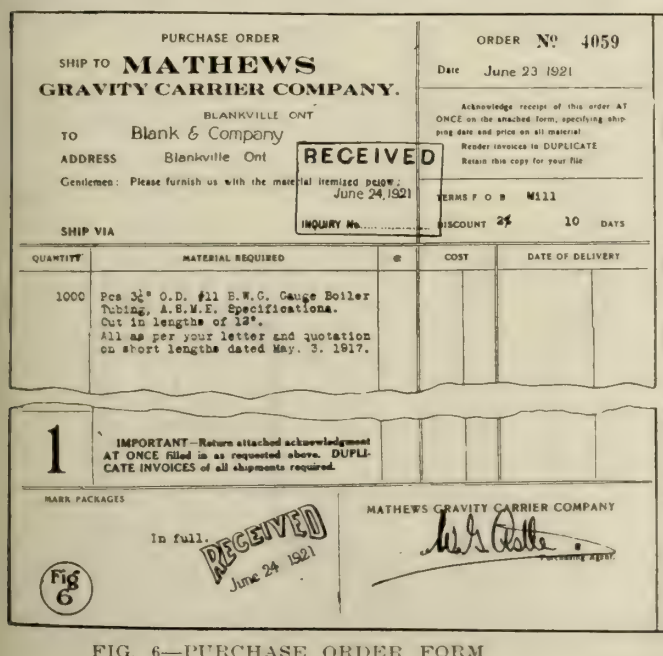
Right buying is like the healthy constitution which pulls you through a serious sickness—you don't think much about it until the doctors mention it. It is the same with buying, you will not know the real worth of your buying policies until they are tested by one of the temporary periods of hard sledging through which business tugs from time to time. Buying is the first point at which profits can be made. It is the first place in the business organization where ability can be shown. Remember, it is no small thing to reach out in the markets of the world and bring together the varied products which are now necessary to make up even the simplest manufactured articles of to-day.

ANNEALING ALUMINUM.

Aluminum castings such as oil pans of motor cars are somewhat difficult to weld when broken, owing to the liability of the part drawing out of shape while cooling or cracking owing to the locked-up stresses. If the art changes shape much it will be impossible to reassemble it, and if held rigidly to a steel frame while cooling off so as to maintain the original form there is danger of cracking.

One of the most effective materials for insulating aluminum castings and for insulating preheated aluminum castings and preventing cracks while cooling down is dry soft wood sawdust, continues Autogenous Welding. The sawdust should be used liberally, covering the welded casting to a depth of say two inches. If dry it is an excellent insulator, and if the casting is quite hot it is likely to take fire and smolder slowly, thus extending the cooling period considerably. An aluminum casting so treated will be annealed so soft when cooled that it can be bent without fracture.

In this connection it is of interest to note a method employed by coppersmiths to anneal large copper and brass sheets and keep them flat. The same method is used for aluminum and monel sheets. After being heated the sheets are laid between dry pine boards and left to cool. The boards are excellent heatinsulators and as the wood chars and smolders for a time the slow combustion helps to maintain the heat. The sheets cool very slowly and when finally cool will be found soft and easily bent.



FIGHTING FUEL SHORTAGE.

In order to meet the prevalent fuel shortage and to make better use of the large quantity of small coal sent out from the pits, some German works are putting up small briquetting plants. These plants save the cost of adapting the furnaces for burning dust and other low-grade fuel. In one such plant, with an output capacity of 24 tons per hour, the coal is screened in a revolving drum and the dustis mixed with pitch ground to powder. The mixture is then heated by steam of 250° to 300° C. temperature, and pressed into round briquettes of about 2½ in. in diameter and weighing about 5 oz. A large proportion of the moisture in the coal is squeezed out in the briquetting press.

The highest monolithic structure yet built is said to be the reinforced concrete wireless tower built at Tokyo for the Japanese Government. It is 660 ft. high above ground and tapers from 55 ft. in diameter at the bottom to 4 ft. at the top. The corresponding thicknesses of the shell are 33 in. and 6 in. The footings extend to a depth of 12 ft. and have an area of about 6,000 square feet resting on gravel and clay. The work required some 6,000 cubic yards of concrete and 425 tons of steel.

In order to check the internal corrosion of pipes conveying hot water, it is much more effective and economical, according to Mr. F. N. Speller, the metallrugical engineer to the National Tube Company, of Pittsburgh, to remove the dissolved oxygen from the water, rather than to use protective coatings on the pipes.

At a German steel works there has recently been erected a single-cylinder steam engine which is stated to be the largest in Europe. The engine, continues Engineer, which is of the uniflow type, drives a three-high 30 in. steel rolling mill, and has a normal rating of 4,000 H.P., with a maximum of 8,000 H.P. The cylinder diameter is 68in., with a stroke of 56 in. The speed is 136 revs. per. min., and the working pressure 130 lbs. The crankshaft weighs 30 tons, and the fly-wheel 90tons. The main bearings are 29 in. diameter and 48 in. long, and are water-cooled.

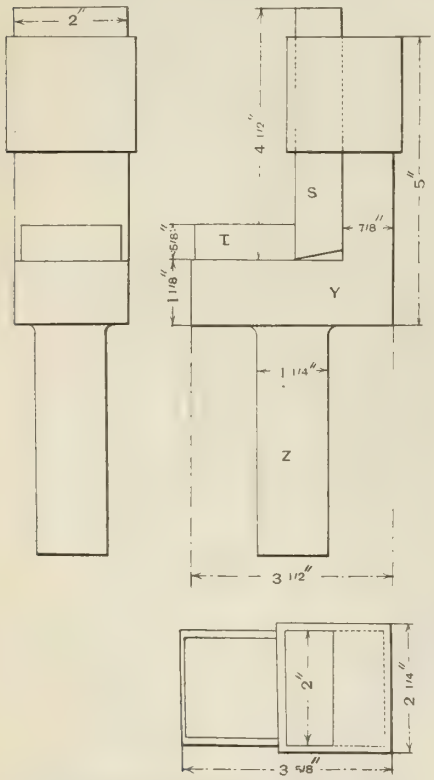
FIG. 7—ACKNOWLEDGMENT FORM USED

Labor Saving Devices in Use in Railroad Shops



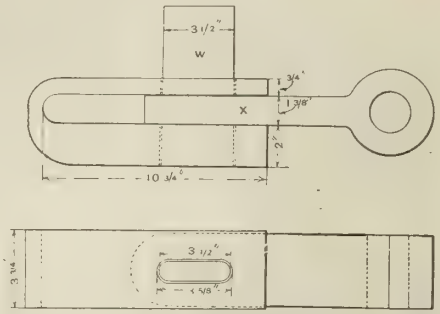
Trimming Cold Chisels—Punch for Strap Hangers—Seat for Dressing Sledges—Boring Air Brake Cylinders on a Wheel Borer—and a Special Wheel Support

QUITE often the use of a very small tool, or a very simple fixture will increase accuracy and production to an amazing extent. Railroad shops are in a peculiar class by themselves, insomuch that the variety of jobs that come to them are much greater than in any ordinary manufacturing plant. This of course means that the workers' ingenuity is often taxed, the result being many ingenious labor-saving devices.

Speaking on the use of such devices, "Railway and Locomotive Engineering" comments as follows:—

Trimming Cold Chisels.

There is a handy little tool in the blacksmith shop of the Erie Railroad at Marion, Ohio, for trimming the ends of cold chisels. It is a one-man affair. Ordinarily, when a blacksmtih has dressed a chisel he needs a helper to strike while he holds the trimmer and the chisel.



DEVICE FOR TRIMMING COLD CHISELS IN USE ON THE ERIE.

With this device he can dispense with the helper. It consists of an L-shaped forging Y, having a square stem Z that fits into the hole in the anvil. The upright portion of the forging has a band welded about it which serves as a pocket and guide for the cutter S. This last is of tool steel hardened and shaped like a shear knife at the lower end. A small square anvil I with a square stem fits into a hole in the horizontal portion of the forging, just as the stem B fits into the anvil.

After the chisel has been forged to shape, it is laid on the anvil D and the cutter C dropped down on it. A blow of the hammer causes the cutter to trim the chisel.

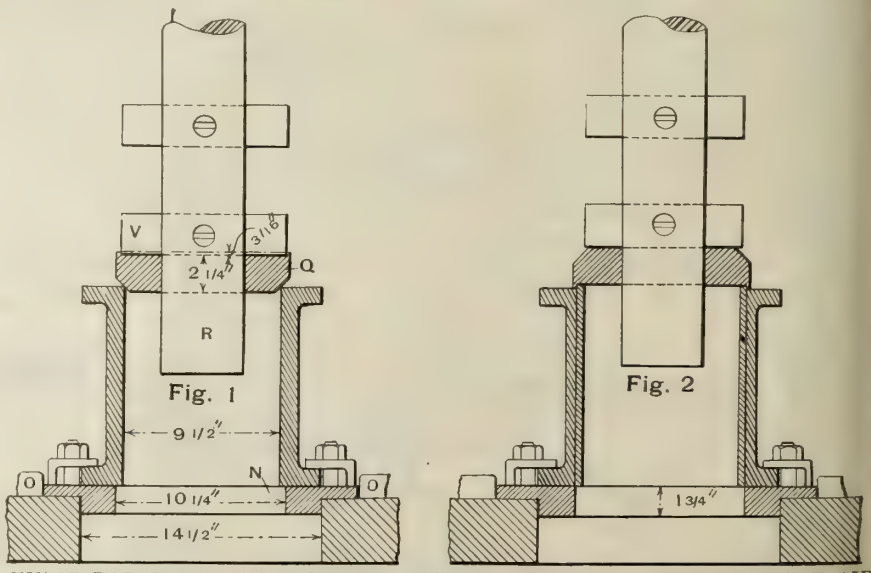
Punch for Spring Hangers.

There is also a punch for spring hangers that is used under a steam hammer for punching the key holes in spring hangers. It consists of a U-shaped forging with one leg considerably thicker than the other. An oblong hole is cut through the two holes

PUNCH FOR SPRING HANGERS IN USE ON THE ERIE.

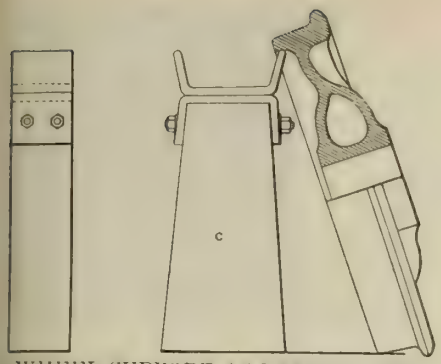
into which a hardened steel punch W is loosely fitted. The spring hanger X is heated and slipped between the two legs, and the punch driven through by the steam hammer.

Seat for Dressing Sledges.



It is a rather long and difficult job for a blacksmith to redress the face of a sledge hammer and give it a properly rounded surface. The simple die, shown herewith, enables the work to be done very quickly under a steam hammer. It consists of a disc about 6 in. in diameter and 1¾ in. thick, into the upper face of which a spherical pocket is sunk. This pocket is about 4 in. in diameter and ⅝ in. deep, struck with a radius of about 3 9/16 in. After the hammer has been dressed, the face end is heated and set on the pocket, when a few blows of the steam hammer on the upturned pene drives it home and gives the face the rounded surface that is desired.

Boring Air Brake Cylinders on a Wheel Borer.



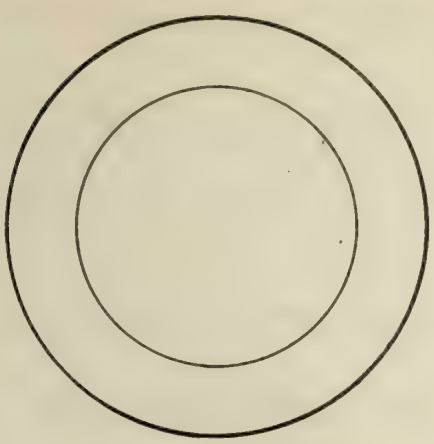
It has been the practice to rebore and bush the cylinders of the Westinghouse air pumps for the whole road at the Meadville, Pa., shops. The volume of this work at last became so great that the department was swamped and the output did not keep up with the demand. In reboring and bushing the pumps a bushing ⅜ in. thick is used. The work was done in a lathe but this was found to be too slow. Accordingly the method now in use was devised.

The machine used is an ordinary car wheel boring machine, fitted with a Davis micrometer boring bar.

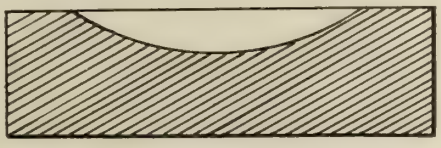
The set up for boring the cylinder is shown in Fig. 1. In this N represents a base plate which is held central on the table of the machine by means of the jaws O of the universal chuck. The cylinder is placed on this base and centered by means of the plug Q which is bored out to slip over the boring bar R. The conical surface is dropped into the cylinder and by pressing down on it with the roughing tool V, it is squared and the cylinder drawn to the center; it being understood that the tools used in the boring bar are squared on both sides, so that as the lower one is pressed down on the plug Q the latter is moved so as to be square with the bar. The plug thus centers the cylinder with the bar, when it is clamped to the base plate with the straps as shown. The plug is then removed and it is bored out to a standard diameter, the tools being set to micrometer measurements in the boring bar. This makes it possible to turn the bushings to a standard diameter by a micrometer gauge so as to insure a uniformity of pressure in putting them in place. They are made a trifle long so as to project beyond the end of the cylinder when in place as shown in Fig 2. The cylinder is placed on the base as before and the plug reversed and set over it. It will be noticed that the upper side in Fig. 1, has a lip around the outer edge. This lip sets down over the

DEVICE FOR REBORING AND BUSHING CYLINDERS OF WESTINGHOUSE AIR PUMPS IN USE ON THE ERIE.

WHEEL SUPPORT AS USED AT THE DELAWARE & HUDSON SHOPS.



end of the bushing and, when the boring bar is run through the hole in the plug, the cylinder is centered. When this is done the cylinder is again clamped to the base and the bushing bored and faced off. It is a unique use for a wheel borer and one that has served to greatly decrease the time required for this class of repairs.



Wheel Support.

In connection with the wheel borer in the shops of the Delaware & Hudson at Watervliet, New York, there is a very simple and handy wheel support to hold the wheel in an upright position after it has been rolled up to the machine and before the lifting tackle to place it in the machine has been adjusted. It consists of a substantial block C bolted to the floor and capped by a U-shaped piece of flat steel the upper end of whose legs are of the proper height from the floor to catch under the rim of the wheel as it is leaned against it as shown in the illustration. This avoids throwing the wheel to the floor and holds it in a convenient position for the adjustment of the tackle.

WATER TIGHT JOINTS.

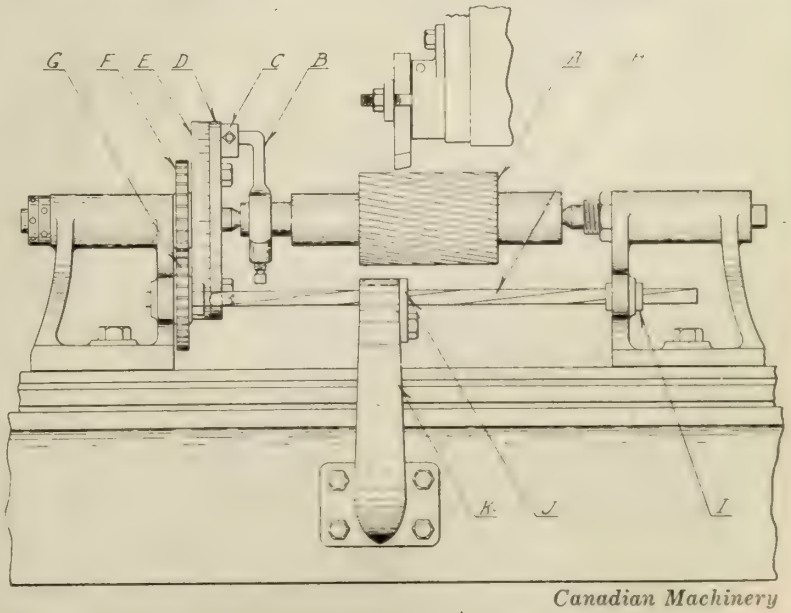
An ingenious system of making water-tight the joints in concrete structures, such as dams, has been devised by Mr. F. B. Smith, of San Francisco. During the process of construction a groove is formed at the joint and is filled with asphalt blocks. The blocks have a hole down the centre through

DISC FOR FORMING FACE ON DRIVING SLEDGES IN USE ON THE ERIE.

which a pipe is threaded and left in place. Two such sets of blocks are arranged close to one another, and the bottom ends of the pipes are connected together. When the structure is finished the asphalt is melted by passing steam through the pipes. If settlement subsequently takes place the asphalt can be remelted and added to if necessary.

BORING, DRILLING AND MILLING MACHINE.

The Jones Machine Tool Works, Philadelphia, Pa., have developed a horizontal boring, drilling and milling machine of the planer-table type. This machine is said to be very useful on such work as boring cylinders, motor housings and other classes of horizontal boring mill work.



The machine may be driven by either a constant or variable-speed motor located at the base of the column. Power is transmitted to the vertical driving shaft through spur and bevel gears, and the vertical shaft drives through a set of heat-treated steel bevel gears and sliding speed-change gears to the bull gear and quill, and thence to the spindle. All of these gears are fully enclosed in the saddle. The saddle is raised and lowered on the column by a bronze nut revolving on a steel screw, the movement being obtained by means of either the handwheel, power feed, or rapid traverse. Provision is made for traversing the main column on its base by hand, power feed, or rapid traverse, the movement being controlled from the saddle. Power for traversing the column is transmitted from the saddle gearing to a bronze nut and steel screw; operation by hand from the floor is also possible. A steel scale is set in the front vertical shear to facilitate setting the spindle in line with the outboard column bearing.

The table is also operated from the saddle by hand, power feed, or rapid traverse, and there is also a hand feed from the floor. Centralized control of the saddle is arranged for all levers being within easy reach of the operator. All sliding speed-change and feed-gears, except the bull gear, which is made of electric steel, are produced from 0.60 to 0.70 per cent. carbon steel and heat-treated. All gear shafts are made of steel and run in bronze bearings provided with sight-feed lubrication. The bull gear, in addition to being carried by a steel quill, runs in a large conical bearing that takes the thrust when using a faceplate, milling cutters or facing attachments.

The spindle is made from 0.60 to 0.70 per cent. carbon steel and has a standard Morse taper bore at the front end. It is supported by the quill and a steel clamp bushing which runs in the bronze-bushed rear slide. Thrusts in either direction are taken by large bronze thrust washers located on the faces of the rear slide. The feed to the spindle is accomplished by a bronze nut in the rear slide, acting in conjunction with a steel screw. Power feed gears are all located in the front cover of the saddle, and are provided with a friction safety device. The rapid traverse is also of the friction type, and provides against breakages, should the spindle, saddle column, or table become jammed when at the end of one of their respective traverse movements.

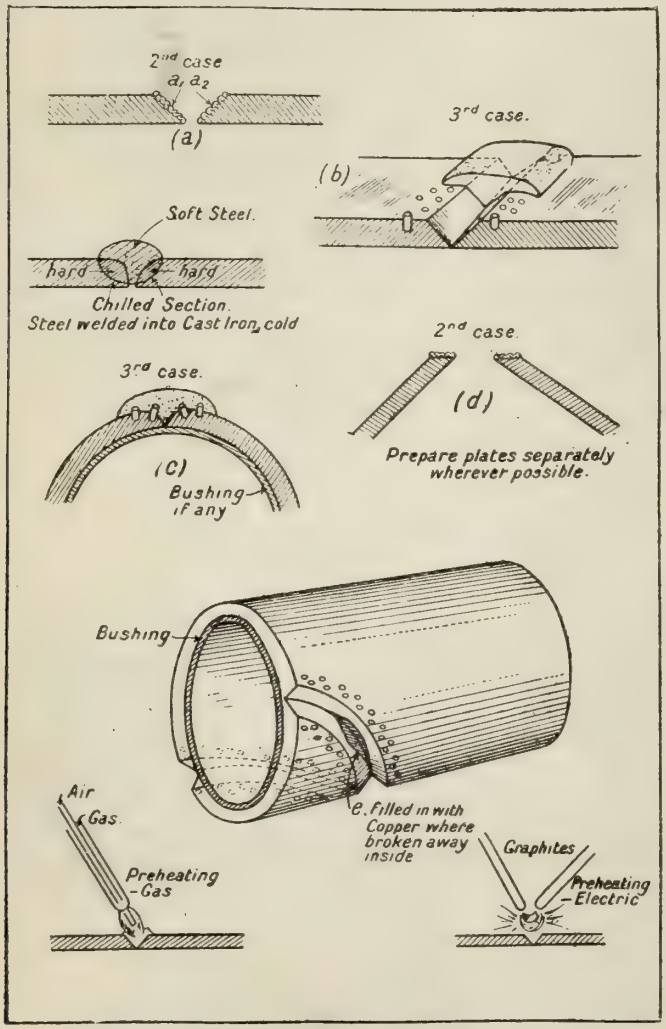
Planing Helical Grooves

The sketch illustrates a fixture used on a planer for cutting helical grooves on a crusher roll. The work "A" is supported on centers. On one end is the driving dog "B," the tail of which is located in the slot of the lug "C"—back lash being taken up by the small set screws. Plate "D" is independent from plate "E," and may be revolved by slackening two nuts, the bolt heads moving in T-slots in plate "E." Plate E and gear "F" are keyed to the spindle in the drive head. Gear "G," which meshes with gear "F," is secured to the square twisted (and milled) shaft "H," this shaft being supported in lugs extending out from either head, the bushing "I" in the right hand head providing a cylindrical bearing. "J" is a flanged bush fitted to shaft "H" and secured to bracket "K." This bracket is bolted to the planer bed. Movement of the planer table rotates roll while tool is cutting. Adjustment for different cuts is made by movement of plate "D" to the desired setting, graduations being provided for this purpose.

Canadian Machinery

WELDING AND CUTTING

Welding of Heavy Sections by the Electric Arc



This Method, if Attacked Systematically, Should Prove Easy—Instructions for Preparing the Work to be Welded—What to Avoid—The Welding of Cast Iron is Classed Under Four Heads.

THE welding of heavy section is something which some welders unfortunately fall down on. When attacked in a systematic and common sense manner however, no trouble should be experienced and the following information, which has been taken from a recent book on *"Electric Arc Cutting and Welding" by alternating current, should aid readers to master this branch of welding.

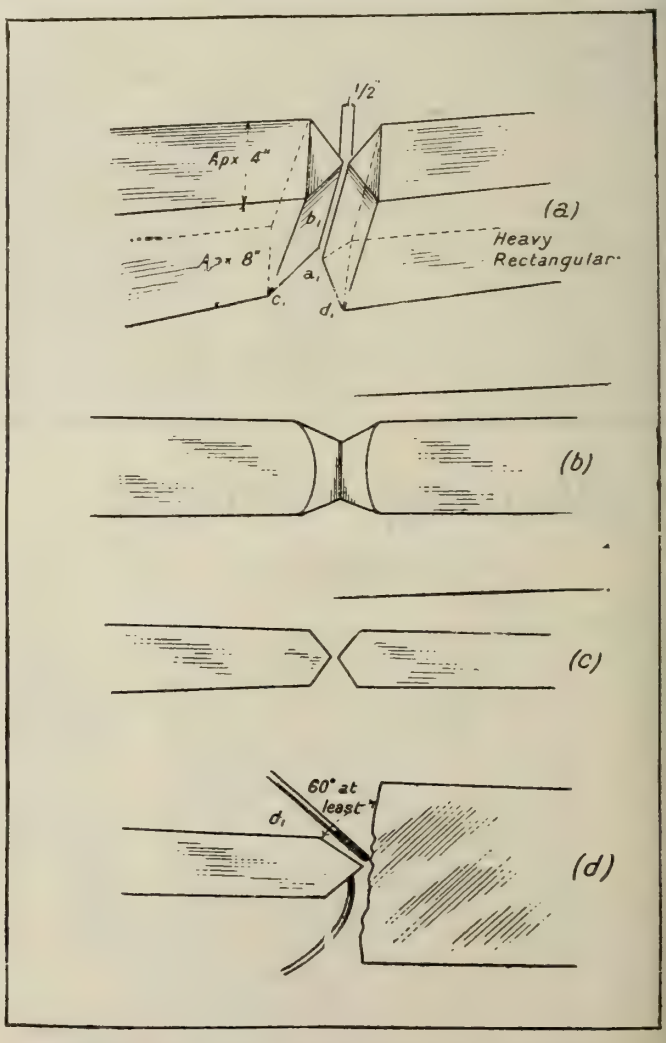


Fig. A shows how a large section can be successfully joined by electric arc welding. It will be noted that the smaller dimension of the section is "veed" into a double V by machining or gas cutting or electric cutting. If the job is such that it can be turned, i.e., rolled over, a smaller or similar "V" should be made on the other two faces, and if it can be rolled over this "V" should made on the top face as shown in Fig. A, so that the length of edge abutting is somewhat reduced.

A section like this, however, should never be brought to a pencil point as there is then infinite chance of its becoming warped out of alignment during welding, whereas with a chiseled edge preparation of each piece is shown, there are only two chances, when once properly lined up and tacked of its being drawn out of line by expansion in welding. The piece should be tacked at the top, bottom and middle of the chiseled edge, and the entire length of the chiseled edge filled up from the side opposite to the tacking, then welding from the other, or first side. Add two or three layers or beads, proceeding from side to side as in the direction, A-1, D-1, A-1, C-1. When two or three layers have been added on this side,

SHEET COVERING THE WELDING OP CAST IRON

INSTRUCTION SHEET ON WELDING HEAVY SECTIONS.

proceed to the other side and add approximately twice as many, then proceed to the first side and add twice as many on the other side and so on by degrees from each side until the job is finished. This is to prevent the original alignment being pulled out of place by the contraction of the welding method.

Where the two pieces of the parent metal, or one of them is non-rigid, during the welding, they may pull out of alignment, but if the welding is equally done and not too much increments from either side, the resulting alignment will be reasonably perfect. A way of insuring the alignment as near perfect as possible is to have two men weld at the same time and at the same rate, one from each side.

This is especially applicable to large pieces symmetrically arranged, and where the time of one man welding would cover more than a day's work, or where rush work is required and costs must be sacrificed in welding a job of this nature. For subsequent machining it is practically impossible to have the weld and parent pieces alignment sufficiently for machine fitting or bearing alignment. In this case one of the pieces, or both, should be larger than the finished size, or a pad of welding metal can be added all round, or on the low side so that subsequent machining to the correct size can be accomplished.

The greatest care should be taken, however, in lining up the pieces so that this bead or excess of metal required should be a minimum. In welding a broken crank shaft by the use of "V" blocks passable jobs have been made without this addition in metal, yet it is much simpler and surer to pad the entire surface and machine all over to the correct size.

Circular Sections.

Figures B and C show the method of joining circular sections. Here the mistake is often made of preparing the two ends to a pencilled point instead of a chiselled edge. As explained, it is very difficult to get true alignment even with the chiselled edge preparation; with the pencil point preparation, or as might better be termed centre punch preparation, there is absolutely no chance of ending up even with a reasonable amount of padding or excess metal to be machined. This does not come from the inability to line it up perfectly from the beginning, but the impossibility to equalize strains in the welding metal. In welding large sections, too great a bite into the parent metal on either side of the "V" should not be made at once, i.e., the amount of the parent metal bit into in each layer should not exceed the width of one bead.

This for two reasons:—1. That too great a leverage for pulling out of line is not allowed. 2. If the parent metal is covered with the weld at the start the "V" after the second or third layer will become too narrow to do proper welding, i.e., to be able to hold the electrode at approximately right angles to the face to be welded.

Where the bottom of a large section is inaccessible a plate can be put at the bottom; starting either underneath and flat up against the section or the plate veed out as at C-1, A-1, D-1 to provide a foundation for the successive layers. A succession of these plates could be provided, successively welding one on top of the other until a laminated joint is made. This method is used by some engineers to weld engine frames, making the laminations up out of scrap boiler plates; while others are using the solid weld and fill in a section with an equal or better success. If the weld is properly made it is obvious that this is the better method as a 100 per cent. section is thus obtained; whereas the laminated method is too similar to the process known as "slugging" which should not be countenanced in any method of welding—but often used in filling in large sections or holes. It consists of putting in solid pieces of metal such as slugs, burs, washers or rivets and then filling in around with the weld and presenting at the finish an apparently beautiful job. Obviously the inner section is valueless and the job fails in time to detect the guilty party. This process should not be mentioned to operators, as it is bad in practice: it will probably be met with sometimes. There are a few cases, however, where slugging is permissible:—

1. Where a finished surface only is desired and no strength need result. 2. Where a reinforcing member is added as a longitudinal bar welded along a member under bending strain, to reinforce its centre section as a strut, where its bending moment is greatest.

If a job is welded and it breaks in the weld, and the weld seems to be perfect, the break of the original bar and the breaking of the weld show that the section is not large enough. If a slight increase is necessary or allowable, it can best be put on by a pad of welded metal, but if a considerable length of section is to be put on, it is sometimes advisable to apply the section by new good metal welded by fillet or "veeing" to the size desired.

Avoid This Method.

Figure D shows method of preparing a joint which is to be avoided. Sometimes it will be met, especially when joining to a section much larger, or to a flanged section where the break is very close to the flange. In this case the angle of the chiselled edge must be greater and more nearly equal to the double angle when prepared from both edges. Even when this angle is such, great care must be taken that the weld is made to the vertical heavy face carefully, and for this purpose sketch D shows how wire can be bent into a shape which will assist in this. A joint made in this manner has not the chance of being as reliable as a joint made as in A, B, and C, because more surface is available on one of the pieces to be welded to than on the other, and because there is no chance of an overlapping fillet on the larger piece, where it is most needed.

In the case where the large piece is cast iron or both pieces are cast iron, steel studs can be used to advantage.

Welding Cast Iron.

Welding cast iron might well be classed under different heads. For this reason we will consider the subject in the form of examples or cases.

We will consider the first case, where the method is used simply as a means of filling in, or building out, where grinding is the only machining necessary. Clean out the spot to be welded by chipping or grinding so that all dirty, oily, sandy, or porous metal is cleaned away and a reasonably bright metal foundation is provided for the weld. Weld with either steel or cast-iron electrode according as to whether a reasonably hard or a very hard surface is wanted after grinding. The steel gives a hard surface and the cast iron a very hard surface. Care must be taken in using the cast-iron electrode that the quick cooling does not catch gas bubbles in the weld leaving holes after finishing. The steel causes no such trouble, but if one or two imperfections show a peening hammer will close them up.

Second Case.

Welding cast iron where tensile strength is required, but no resistance to bursting pressure will be experienced, i.e., welding broken machine-parts, bedplate, etc. In general where no undue strain results, and the part was originally broken by some accident which will hardly happen again in the same place, i.e., "V" out wide enough so that the electrode can be held at approximately right angles to either face of the "V." Weld the two faces of the "V" separately with steel, using great care to have the steel united to the face as the arc progresses and not let any of it run down ahead of the puddle; weld from the bottom up, and, if any of the deposited metal does get away stop and chip it off. After the two faces are successfully covered, it is extremely easy to make a good weld from the steel faces, using steel or cast iron in the "V."

Third Case.

Welding cast iron where heavy bursting pressure is to be met or great tensile strength is required. Use steel studs in single or double row either side of the "V," i.e., from 1 in. deep on the upper half of the "V." The studs to be ⅜ in. to ¾ in. diameter depending on the size of the work, to be screwed into a tapped hole from ½ in. to 1 in. deep, according to the thickness of the work. Saw off ⅛ in. to 3/16 in. above the surface of the work.

First:—Carefully weld round the studs so that the studs are part of the cast iron, then weld diagonally as in lacing a shoe across the weld from stud to stud, and finally finish as with a pad over all, completely covering the studs. In general, studs of steel are needed in a number so that their cross section by 60,000 lbs. their strength equal the cast-iron section by 18,000 lbs. its strength, i.e., about one-fifth area of steel studs to the C. I. for a 100 per cent. job.

The first welding from stud to stud draws the casting together into original contact, especially if a small amount of the original break is left intact at the bottom of the "V." This can be done except in the instance where the piece breaks out and is lost, as in engine cylinder wrecks. A bottom of copper forced in with an air hammer should be used so that for subsequent machining the chilled cast-iron surface under the weld will not be met. In general, much more satisfaction can be had by introducing a bushing especially in large cylinders, which bushing makes the piston fit the weld simply taking the bursting strains. Many cylinders are supplied with the which bushing makes the piston fit the bushing should be removed and replaced after the welding job is finished, machining slightly to size if necessary.

Fourth Case.

Welding cast-iron for subsequent machining through the weld. In all the foregoing cases the weld may or may not be machinable, but the chilled layer of cast-iron directly under the weld will seldom be machinable except for very thin pieces, due to the cast-iron having been heated and chilled quickly and uncombined carbon left in its graphitic state.

To remove this hardened layer when

WHAT OUR READERS THINK AND DO

PROPORTION OF STAIRWAYS.

By JOHN S. WATTS

IT often happens that stairways are required, and that rather than get the work done by some outside concern, the shop tackles the problem itself. Judging by the awkward, in fact dangerous design of some stairways, I am convinced that definite data on the proportion of stairways would not be amiss.

In architectural work, the staircase is always an important part of the design, indeed in some cases the most important, being often the central object upon which much thought is expended to create an impression of grandeur. In mechanical structures, on the contrary, the stairs are necessarily relegated to the lowest place, being usually placed in the design after the more important matters, such as the machinery, engines, etc., have been placed, and the stairs must be located where space can be found for them, or wherever they can be crowded in.

Under the circumstances that control the dimensions of buildings for housing machinery, which must be made to suit the machinery, it is impossible to standardize the dimensions of the stairs, but a knowledge of the limiting factors that determine the ease and safety with which stairs may be used will be of considerable help.

The accompanying table shows the proper width of tread that experience dictates as the most desirable for any given rise, the rise being the vertical height from one step to the next, and the tread, the horizontal distance face to face of risers. The last line in the table shows the ratio of rise divided by tread for each step, and enables us to pick out the combination which the space in the building will permit.

Referring to Figure 1, we will take as an example, a case where the vertical height from floor to floor is 12 feet, and the maximum horizontal length available for the stair is 18 feet. The ratio will be 12/18—.666; and from the table we pick out the step having the nearest ratio, namely .67, which has a tread of 10 inches and a rise of 6⅝ inches, as the easiest stair way we can get into the space allowed. We note that in Figure 1, there is always one less tread than there are risers, and that if we wish, we can add one tread to the horizontal length in making out calculation of the ratio. This would make the ratio $\frac{144}{216 \div 2} = .637$; which will permit the use of a stair having a 10½ inch tread with a 6¾ inch riser.

The dimensions of stairs given in the table cover all those that should be used, as the lowest ratio given, namely, 12 inches tread, by 5½ inches rise, is as easy a stair to climb as can be made, and cannot be improved upon by either lengthening the tread or reducing the height of the riser. At the other end of the scale, the stair having a 9½ inch tread and 7 inch rise, is as steep as a stair should be, anything steeper than that is a ladder, and will be safer and more comfortable to use if made as a ladder without risers, and having treads only.

The best width for a stairway is purely a matter of the traffic which will pass over it, but should never be less than 18 inches, and as the stairs given in the table can be safely travelled down with the hand resting on only one handrail, the width may be made as great as the traffic may require.

Ladders being steeper, require for safety to be limited to a width which will permit taking hold of both handrails, and for this reason, should not be made over 24 inches wide. Where space is limited, this width may be reduced to 18 inches. The steps of ladders should be 9½ inches apart vertically, and for ladders up to 18 inches wide, the rungs may be made of two ⅝-inch diameter bars, spaced 1½ inches apart horizontally. Wider ladders are better made with cast iron treads about 5 inches wide, the width depending upon the inclination of the ladder.

HOW DO THEY CUT THREADS IN WOOD?

By D. A. HAMPSON.

Frankly, I do not know how they do it. Two or three times such work came our way and we tried in vain to cut the thread, as it is cut in metal, but to no avail. Naturally, we used tools with more top rake but the wood would break off and we would lose the top of the threads in spite of our efforts; and we even attempted to recut one of these poor threads with a die! We tried the tool method with soft wood and with hard. Finally we decided to turn down such work in the future because very few customers want to pay for spoiled work.

But when we could not get replacements for broken wood screws in the parallel clamps the pattern maker used, we decided to attack the problem more deliberately. A little block was made to go on the lathe cross slide; a hinged piece was used on this block, also a file. The file was clamped in the hinged piece—it became our cutting tool.

The lathe was geared for the wood screw thread and the block swivelled to the thread angle. Instead of cutting the thread, it was filed in by pressing the edge of the file in the blank as the carriage moved to the desired pitch. The operation proved that the saying, "You can file what you can't cut is as true for wood as it is for metal." To prevent the finished thread being oval and to get a constant diameter throughout the length, the block of wood was set at the back for a depth gauge, or stop, for the file. Pressure for the file was obtained by the hand at the top end of the hinged piece. On the return movement, the file was lifted.

Following this successful threading job, others were accomplished in a similar manner. Either a half round or a three-square file was used, the shape depending on the angle of the thread. Neither file produces our familiar 60 degree thread to a nicety on account of the angle of the file shape, and the fact that there is a slight drag when a long piece like this is laid across and below the surface of a cylinder—much as an angular cutter does not reproduce its shape on a spiral milling job; but in the case of wood threads, the results are close enough, besides it was possible by this method to turn out acceptable, whole threads.

PORTABLE GRINDER.

A portable pneumatic grinder has been placed on the market by the Keller Pneumatic Tool Co., Grand Haven, Mich. This grinder, which is known as No. 22-G, is provided with a rotary-piston type of motor. The grinder is built in two sizes, the smaller weighing 5¾ pounds, while the larger type weighs 18 pounds.

The Danger of Too Free Credit

ON Page 39, June 23rd issue of Canadian Machinery, we published a short article by Elbert H. Gary, chairman of the board, United States Steel Corporation, on the subject of "Good Times are Actually Here." The author further on in that article speaks on the danger of too free credit, and here are a few of the pertinent points brought out:—

Too free credit is not good for business. It is about as destructive as unduly tight credit and because it permits expansion without much regard for repayment of the money borrowed, excepting through the continuation of ever-increasing prices, it leads eventually to a crash. It is fortunate that our banking system was able to avert this crash which was at one time imminent.

Too free credit not only tempts toward extravagance, but it tends toward confusion of thought as to the right use of credit. If one can discount an apparently unlimited amount of paper, the way is indicated toward using purely commercial and what is supposed to be self-liquidating credit for capital uses. Then when the day comes for repayment, high-cost, emergency financing must be had to fund in some manner the capital which has been borrowed under the guise of credit. This has been happening to an unusual extent and where the fresh capital could not be had reorganization has been necessary.

It is not safe to borrow money on short-time obligations unless that money can be repaid out of the sale of the goods. Capital borrowing against surplus earnings that are expected in the future is never sound business and it is particularly dangerous business when it seems most feasible —that is, in a rising, boom market. For then the risk of non-payment is greatest. One must have capital in order to do business. Nothing has happened to change that elementary fact. Nothing will happen. The shareholders and the bond-holders, not the banks, are to be looked to for capital. The banks perform their whole service when they lend the the money with which to carry goods through the processes of fabricating up to final sale. Or they can carry sound securities in the same fashion—whether of new or old issues.

Safety Rules For The Factory

SPEAKING on the need of "Safety Rules for the Factory," George Swetman in a short article in American Machinist, offers ten rules that are well worthy of consideration. Here they are in the order given:—

1. Open high voltage switches and transformers should be enclosed, or at least fenced off from the rest of the factory. Prominent signs should also be posted.

2. Concealed wiring is less liable to receive damage which will cause fire or accident than is open wiring. Use it. It is also well to protect all bus bars from possible falling wires, etc.

3. Forbid workmen to crawl through narrow, moving belts. This seems foolish but if you will watch you will be surprised at the prevalence of this little short of lunatic performance.

4. Never run a boiler at a pressure higher than its rating without the advice of the maker. The same is true of superheaters and engines.

5. Most boilers are kept too full, as this does much to prevent explosions. It causes priming, or water in the steam, which is likely to cause broken piston-rods, cylinders, and cylinder heads, and scored pistons and cylinders to say nothing of making packing renewals very frequent. Avoid this trouble by having the chief engineer look the boilers over frequently.

6. It happens once in a while that a lazy fireman keeps his boiler only about one-half full, being under the false impression that so doing makes firing easier. As this is only courting explosions it is best to dismiss such a man at once.

7. Never allow machines to be cleaned while running. Any number of one-armed men could testify to the foolishness of such an act. It is still sometimes done.

8. Don't let bearings stay loose. They endanger life and property by causing broken shafting, and are responsible for loss of power.

It seems useless to say this as it should be an axiom, but I know of one man who ran his plant with an important bearing loose for more than a month, cutting down his production perhaps as much as 25 per cent.

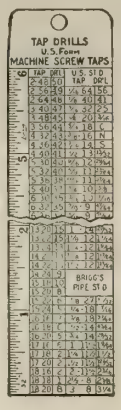
9. Bar all irresponsible people and children from your plant while it is running, unless they are accompanied by a careful escort.

10. Don't wait until an accident occurs to put these rules into operation. You are responsible for the safety of all concerned. Act!

The Value of Common Sense

SPEAKING on the value of education to engineers, Knox Taylor, C.S.C., president of the Taylor-Wharton Iron & Steel Co., stated some valuable truths, some of which appear below.

"An engineer,"said Mr. Taylor, "should be educated to know a great deal about a few things and a little about a great many things. Where should the line be drawn? That is the great question. To draw it properly is a matter for judgment, and good judgment is so rare! How much time, money, and even life, is wasted through poor judgment! Too much emphasis cannot be placed on educating to develop good, sound judgment, for without it nothing else avails.



"Good judgment is often called 'horse sense' or just plain, good common sense, and how many so-called well educated men we meet who do not have it. A man who does not possess it in at least a considerable degree is just not an educated man, and cannot be an engineer in the true sense. Good judgment is obtained only in part from books or the laboratory. It is obtained for the most part from the fullness of life's experiences. A full life must have lots of study, with a lot of other activities. Some of the studies must be thorough and intensive, enough so that the student will realize that much that has been pointed is either wrong, or, upon proper analysis, points to some entirely different conclusion than that previously assumed. This develops individual thought and judgment through analysis and discrimination. Every subject cannot be so fully studied, but ordinary study in any one subject helps to acquire education by only a general or superficial study of other subjects. The other activities in a man's education, outside of study or laboratory work, should develop the human side, and how to get results for, with and through other people.

You see so many men who cannot get on well with others. They may be wonderfully well informed scientifically or technically, but they are not good members of a group or team. They are not cheerful, courageous, or considerate, or they have been too busy (with less important things) to learn how to secure any one or all three of these Christian characteristics.

What I have said applies to learning all through life, but of course especially to the school and college age. I think I have made it evident that in my opinion the engineer should have the broadest possible foundation. If this is sacrificed to a great deal of early trade or technical work, time is gained at first and lost later, never to be made up again. What a rich world this would be if only we could profit more by the experience of others. So many lack the judgment to do it.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Owing to the Armstrong Bros. advertisement being switched at the last moment, the contest for June 23rd issue of Canadian Machinery, became obsolete, insofar as question No. 2 was concerned. This query read "A very essential quality in a W—? The answer was the strength contained in wrenches, but as already stated the advertisement to suit the query did not appear. To make up for this omission, we will award two prizes for the July 7th contest.

CONTEST FOR JULY 14TH ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something you can't help noticing.
2—An interesting piece of information.
3—A purchase that involves an important question.
4—Something that refers to the high cost of lumber.
5—How to save time and labor.
6—A product that has resilient packing.
7—A case where there is a weight for every pressure.
8—Something that started 32 years ago.
9—Where time is expensive.
10—How to tell a good machinist.
11—A case where a leak means dollars wasted.
12—Something said to stand steady heavy pressure duty.

These are Correct Answers for List from June 23rd Issue.

1—John Bertram & Sons Co., Ltd.
2—(See special note).
3—S. F. Bowser Co., Ltd.
4—Dalton Mfg. Co.
5—Elk Fire Brick Co., of Canada, Ltd.
6—W. H. Banfield & Sons, Ltd.
7—Rice Lewis & Son, Ltd.
8—Kearney & Trecker.
9—United States Electrical Tool Co.
10—Selson Engineering Co., Ltd.
11—The Bristol Co.
12—Audit Bureau of Circulations.

Closing Date for This Contest is Aug. 4th

DEVELOPMENTS IN SHOP EQUIPMENT

NEW LATHE.

A newly designed heavy-duty, triple-geared lathe of 60-inch swing has been placed on the market by the Houston, Stanwood & Gamble Co., Cincinnati, Ohio. The bed of this machine is a one-piece casting, 42 feet long, and the total weight of the lathe is approximately 40 tons. The machine is driven by a 35-horse-power variable-speed motor mounted on the headstock. An additional motor is furnished on left end of the apron, affording rapid power traverse to the carriage. Two steady-rests are provided, the larger having a capacity for work from 23 to 37 inches in diameter, and the smaller, for work from 2 to 23 inches in diameter. The jaws of these steady-rests have bronze shoes.

The various spindle speeds are obtained by operating the levers and handwheel on the headstock, and the different positions of these are designated by letters to enable an operator to determine a speed readily by referring to this speed plate on the headstock casting.

The majority of the headstock gears on this machine have a pressure angle of 20 degrees. Lubricant is delivered to the headstock by means of a pump mounted at the rear of the lathe, which is driven from the motor shaft. To insure that the oiling system is functioning properly, an indicator is located on an oil-feed line from the pump to the headstock. This indicator has an aluminum wheel which spins rapidly when oil is flowing. The wheel may be observed through a glass at the front of its container. A device is provided to prevent oil from flowing up on the motor pinion and leaking out through the housing.

Starting, stopping, and reversing of the motor on the headstock are controlled from a controller mounted on the right-hand end of the apron. The action is transmitted through the horizontal shaft near the bottom of the bed and through sprockets and a chain at the right-hand end of the bed, which connect with a second horizontal shaft at the rear. The feed mechanism in the apron is driven through a positive angular-tooth clutch. This clutch permits feeds to be instantly engaged or disengaged without excessive strain on the operator's wrist. Both the front and back walls of the apron are bolted to the carriage.

In a test on this machine a cut 1⅞ inches deep was taken on a 16-inch diameter, 0.50 per cent. carbon, hammered steel forging, at a feed of ¼ inch per revolution and a speed of 15 feet per minute. The cross-sectional dimensions of the tool used were 2 by 3 inches, and its length 20 inches.

MEASURING MACHINE.

Various improvements have been made in the design of the precision measuring machines made by the Pratt & Whitney Co., Hartford, Conn.

For example, pedestals can be supplied for the 36 and 48 inch machines, and in addition two brackets are furnished which support a wooden shelf mounted between the channels, thus affording a convenient place for holding work to be measured. A tangent screw has been provided for the measuring head that facilitates making very fine adjustments of the index-circle. This was formerly accomplished by a knurled knob at the rear, but the tangent screw with its multiplied leverage supplies an easy movement, so that it will be easier to bring the anvil up to the measuring point without going by. A magnifying glass has been mounted over the index-circle, so that the measurement can be seen more accurately. When desired, a vernier may be added to the zero line for the index-circle, which will provide greater accuracy. The microscope on the objective tube has been improved, and a small electric light has been added at the bottom, to illuminate the cross-line of the microscope and the objective line which is etched on the plug of the standard bar.

ATTACHMENT FOR MILLER.

An attachment for their No. 102 pattern milling machine has been placed on the market by the Oliver Machinery Co., Grand Rapids, Mich. This attachment consists of a complete set of appliances for cutting teeth on the patterns of spur, spiral, bevel, and worm gears. The outfit consists of a special 14-inch universal dividing head, tailstock, index-plate, index-chart, 6-inch faceplate, 12-inch faceplate, a set of raising blocks, change-gears, quadrants, and a mechanism for driving the dividing head. The attachment is so designed that in turning a pattern for a spiral gear, the pattern is rotated according to the angle of the spiral as the cutting tool progresses across the face of the pattern.

The Return of The Miners

THE return of the coal miners throughout Great Britain should have a world-wide effect. Now that the strike is over and the men are back at their tasks, they no doubt see the folly of their past actions. This will be especially true of those who are eager to return to work, yet find that the mines in which they were formerly employed are so badly flooded that it will take considerable time before they are fit to be worked. In some cases mines have been totally ruined, and will never be worked again. It is to be hoped that this condition will be an object lesson to those who advocated drastic action during the strike and who were largely responsible for the sabotage perpetrated.

Let Britain once ge to work in earnest on her coal industry and the results of her activities will be world-wide. For example, suppose for a moment the mines to be in first class shape and the workers producing at a better rate than they ever did before. This is to be expected, as the men will go back with a new zest. What then will be the natural consequences?

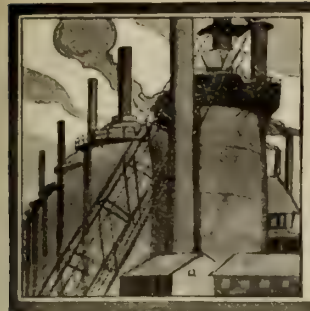
As soon as Britain can supply her own industries with cheap coal, the price on British goods will be lowered accordingly. This will mean that she will be in better condition to compete in the world's markets. Once having supplied the home industries, the coal owners will again start exporting to all parts of the globe. This in turn means cheaper coal for the various countries, with a correspondingly lower production cost, allowing them to market their goods at a lower price. Britain and other countries will be able to establish large credits because of their increased business activities, and it will also mean that the mercantile marine of the various nations will prosper exceedingly. Employment will be found for those running the ships, those loading and unloading, and the shipping industry will benefit generally. Freight rates will be lowered, which again helps the manufacturer to market his goods at a better price, this in turn meaning that industrial conditions throughout the world will improve. The far-reaching effect of the re-commencement of the coal industry can hardly be overestimated, for indirectly it will influence the general downward trend of prices, and add a little more grease to the slide down which "Old High Cost" is still dropping.

Watching The Details

THE details of a business should receive just as close attention as the larger matters, for to make any concern a financial success, the money leaks must be closed up; otherwise the finished product cannot be turned out economically.

All this may sound very prosaic, yet in spite of the above fact being known, considerable waste is allowed to exist in many plants, even in these days of keen competition. For example:—In passing through a plant recently, a miscellaneous mass of material was noted in a pile in one end of the building. On enquiry this was found to be "Shaft Ends." Two words, but what a story could be told were it possible for shaft ends to speak.

In fancy we hear one of these ends say:—"Do you know that every year there are over 6,000 pieces exactly like I am sold to a junk dealer? True, we are too short to be of any actual use for any parts made at this plant, but I know we could sell for better than shaft ends to some other firm who could use us to good advantage. Instead of that we are carelessly dropped in a pile and left until there are a sufficient number of us to sell as scrap.



"If that purchasing agent, whoever he is, would only think:—We are only 1½ inches too short. Why can't he order our complete bars longer, even 3" more in length if he cannot get us 1½" longer. Better to waste 1½ inches, than over five. He would find before the year was out that he had partially paid his own salary by the saving effected.

"He may say that shafts come in standard lengths, but ordering as we do, such large quantities, I feel sure he could arrange for a suitable length of bar."

How about this fanciful tale of the shaft end? Does it apply to you, Mr. Manufacturer? If so, study your parts, see what you can do to stop the often ignored bar waste, thus eliminating a constant source of annoyance.

GOOD ADVICE—BUT————

MARKET DEVELOPMENTS

PITTSBURG BELIEVES BOTTOM HAS NOT BEEN REACHED IN STEEL PRICES

Syecial to CANADIAN MACHINERY.

PITTSBURGH, July 14.—The fourth general decline in steel prices since the period of Government price control has just been completed. The first decline was by way of the voluntary reduction made in December, 1918, while the second was that brought about by the Industrial Board appointed by the Secretary of Commerce, effective March 21, 1919. In 1920 there were great advances by independents but the Steel Corporation did not advance its prices, so that the recession in independent prices late in 1920 to the Steel Corporation level was not in one sense a market decline. The third decline came from about February 1 to the middle of April of this year, the independents shading prices more and more until eventually the Steel Corporation made reductions and the market was made uniform. In June some independents began shading again, in certain products. This grew more extensive. On July 5 the Bethlehem Steel Company, one of the three largest independents, announced formal reductions in its asking prices on bars, shapes, plates, sheets and tin plate. Some of these reductions did not go altogether as far as the open market had gone, plates being a conspicuous instance, while some of the reductions, particularly that on black sheets, went below the open market. The Steel Corporation then adopted the reduced asking prices announced, and went farther by reducing pipe and wire products.

On pipe, wire and black sheets the market is now lower than it was before these formal announcements. On the other products it is a question whether it is any lower, but the upper limit, the ostensible or nominal prices, are reduced. Possibly the formal reductions are announced in an attempt to preserve the semblance of there being a plain and clear-cut market instead of a purely open and competitive market, but a more cogent reason probably was to make entirely public the price declines that had actually occurred, so that when mills reduced wages, as they are doing, they could not be charged with receiving higher prices than they really were receiving.

Prices in Detail.

What is commonly called the "April schedule" of steel prices was arrived at by the independents making slight advances in most products, after their extensive cutting of the Steel Corporation or Industrial Board prices, and the Steel Corporation then making certain reductions in its prices. Since then there had been two general declines, one in wire products, the other in sheets, $5 a net ton in each case. On other products the formal reductions just announced are from April prices. These reductions include $4 per gross ton on billets, slabs and sheet bars, making billets $33, slabs $34 and sheet bars $35, Pittsburgh or Youngstown. Several weeks ago sheet bars sold at about $35 delivered, so that presumably these new asking prices could be shaded. Other reductions from April prices are $4 per ton on bars, shapes and plates, making bars 1.90c and shapes and plates 2c. As early as the middle of June plates had been done quite freely at 1.90c on moderate sized orders, so that it is doubtful whether 2c will really stand as the market. Bars at 1.90c, however, may hold.

Sheets having already declined squarely $5 a ton from the April prices, the reductions just made, in addition, are $4 a net ton on blue annealed and $5 on black and galvanized, making the new prices 2.65c on blue annealed, 3.50c on black and 4.50c on galvanized. It seems quite improbable that the black sheet price will be shaded in the near future. Blue annealed sheets are not so certain, as to the heavier gauges, as they are sometimes sold on the plate mill schedule. As galvanized had previously been sold in some cases at 4.50c when the mills were still holding to 3.75c on black, it is not certain that 4.50c will hold on galvanized when black is squarely down to 3.50c.

Wire products having previously been reduced $5 a ton from the April prices, with in addition a reduction from .70c to .50c in the galvanizing extra, a straight reduction of $5 a ton is now made, making wire in general $10 per net ton under the April prices. The new wire prices are: Plain wire, 2.50c; galvanized wire, 3c; wire nails, $2.75; painted barb wire, 2.90c; galvanized barb wire, 3.40c.

Standard steel pipe had not been shaded by independents to any extent, though there had been considerable shading in line pipe and oil country goods generally. In the case of standard pipe therefore the reduction is a straight reduction by the Steel Corporation of its own initiative. The reduction is from the list of April 13, which carried a basing discount of 62½ per cent. The new card, which is dated July 7, carries a basing discount of 64½ per cent., so that on base sizes the reduction in price is about $4 per net ton, a point being about $2 a net ton, though making allowance for the "trimmings" or extra discount to the large trade a point amounts to somewhat less than $2. In detail, the reduction from the April list is nothing on ene-eighths inch, one point on ¼ and ⅜-inch, and two points on ½ in to 6-inch, sizes 7 to 12 in. inclusive being reduced three points. Galvanized pipe three points. ½-inch galvanized pipe is reduced the same amount as black. Line pipe is reduced the same as standard pipe, and there are general reductions in oil country goods, casing, etc. Discounts on boiler tubes are increased cent.; six points on 2 and 2¼-inch to two points on 1 ¾-inch to 17 ½ per 32 per cent.; six points on 2½ to 3-inch to 43 per cent., and five points on 3¼ to 13-inch to 48 per cent., these prices being basing discounts on less than carload lots.

Striking a general average, the new steel prices are 47 per cent. above their ten-year pre-war average and 30 per cent. under the war control prices.

The new prices are, of course, only temporary. The general feeling in the trade is that whenever there are signs that buyers are getting ready to take hold the mills will voluntarily make further concessions in order to encourage them. In the past few months the feeling among many producers has been that buyers in general did not wish to see prices at mill reduced, since they were endeavoring to liquidate their stocks. If voluntary reductions were not made, the appearance of inquiries of important size would probably lead to price cutting, and a general decline by that route. Eventually, no doubt, steel prices will advance again, but they would hardly advance except by the mills becoming fairly well filled with business, and as the mills are now operating at not over about 20 per cent. of capacity such a condition is not in immediate prospect. The market is likely to remain stagnant for a few weeks more.

Pig iron is down 50 cents, with Bessemer at $22, basic at $20 and foundry at $21, valley furnaces.

Connellsville furnace coke is a shade stiffer, being rather firm at $3, but foundry coke is easier by about 25 cents, being quotable at $4 to $4.50 according to brand.

NEW RULINGS IN THE TARIFFS

Dealers Trying to Find Out What Effect New Regulations Will Likely Have.

TORONTO—One can make the rounds of the iron, steel, and machine tool market without finding much evidence of life. How long can the present conditions last? It is impossible to say. There have been so many false prophets arise in the land that the market is wary of believing any of them. At the end of last year there was nothing short of a regular flock of experts who were

quite certain that the turn of the year was going to see the turning of business toward better channels. There was nothing to justify such a belief, but is became prevalent and popular, at least until it didn't happen. Then there was an equally large number of critics and experts ready to turn around and say that it was quite foolish to expect trade to turn at any given date.

The fact of the matter is that a runaway market is hard to stop. Prices in many lines may be more or less stable, but all that is needed to try them out is that a good sized order shall come up on the horizon when dealers promptly forget schedules and selling lists and are off to make a killing.

New Rulings Cause Trouble.

New customs regulations, which are dated at the 30th of June, are causing steel merchants more or less worry. On shipments that are brought in here from United States, the invoices must bear a footnote certifying that the prices are market values, or cost plus a fair profit. To be exact, here is the footnote, as copied from an invoice going through the Toronto office of one of the largest U. S. concerns:

> "We certify that the fair market value, as shown on this invoice, is not less than the cost of production of similar goods on the date of shipment to Canada, plus a reasonable profit thereon."

"As far as we are concerned," stated the dealer in question, "it is making quite a lot of bother. For instance we started putting this clause on the invoices that arrived here after the first of June, although they may have originally been sent out several weeks in advance of that date. It is a most ambiguous ruling as we see it. No doubt the idea is to prevent dumping of steel in Canada."

As Other Dealers See It.

Brokerage houses have called the attention of all their clients to the new ruling. Here is the way anther dealer sees it: "I can see no good reason for trying to put through such a clause as that now. Surely the government at Ottawa understands that steel, in the great majority of cases, is not being sold at a 'reasonable profit' or any other kind of a profit at this time. As far as the yards around here are concerned, it is a case still of getting the stocks down, at times without regard to fair profits. It would mean that had a jobber a chance to pick up a lot of steel at a very favorable figure in the United States market, he would be barred from bringing the same into this country. There is not a very great deal of shipping being done now, but were a big volume passing the border it would cause no end of trouble."

As Buffalo Sees It.

A Buffalo correspondent, who has seen the ruling in operation at that point, has the following to say about its application, and takes a view that is probably a little more extreme than anything we have come across in the Canadian steel market. Here is his view:

"A situation with reference to Canadian business—always interesting in this vicinity—has arisen and threatens to bring a complete withdrawal of shipments of American-made steel products into the Dominion. The Canadian customs has promulgated a ruling which requires every invoice of steel going into Canada to bear a footnote showing that the shipment is billed at cost plus a reasonable profit. Coming at a time when sales are either at cost or less, shippers here say the ruling is offensive, and that it will result in an advance in prices on Canadian shipments, or withdrawal from that market."

Interest Lags in Steel.

Apart from a discussion of this new ruling the steel market has little to say for itself. The buyer is still very much in control of the market, and he does not hesitate to take advantage of the situation. One hears such incidents as the following: "The purchasing agent of the Blank Company called me up this morning and wanted to know our price on a bar of quarter-inch round." The price of the thing would be well under a dollar, and the firm taking such an order and not charging for delivery would lose money. Another dealer tells of having thirteen orders for sheets, and out of this stroke of business disposing of thirteen sheets, as each order was for a single sheet. These are not isolated or unusual cases. They are rather indicative of the real spirit of the steel market at the moment. Dealers are buying from mills in much the same way. They are afraid to specify heavily, for although little is said openly, the feeling is very much in evidence that the market looks for lower prices, and there may be radical departures from present prices, although they represent several reductions from war peaks. Bars are selling around $3.75 base, although sales are reported at a lower figure. Canadian mills will do around $3.25 on an attractive order. Small shapes are quoted at the same base, $3.75.

The movement in sheets is restricted. Black, 28 gauge, is quoted at $5.70 base; blue annealed, No. 10, at $4.75; Galvanized, No. 28 at $7.50. Cold drawn is sold at $6.00 base. Bands are $4.25 and hoops $4.75.

Boiler tubes are in very small demand and many of the warehouses have extra large stock on their hands owing to the fact the buying has been carried on in a very stinted way. We quote lapweld as follows, O.D.: 2", 23½c per foot; 2½", 30c foot; 3", 37c; 3½", 40c, and 4", 51c.

Machine Tool Market.

Few sales are being made in the machine tool market, although some of the houses state that they have received a number of inquiries, but there has been very little real business resulting from these. The new customs ruling may have a bearing on the machine tool business as well, as an effort is being made to prevent firms taking advantage of the absorption of exchange to evade the anti-dumping law.

Firms carrying a large number of lines are still in a peculiar position over trying to keep up an assortment and at the same time clean out high cost material, and keep in shape to cater to the trade.

The scrap metal market is stagnant, but hardly any worse in the hot weather than it was in the cooler months preceding. Business is done in a small way, the volume is small and the figures involved are simply a matter of arrangement between buyer and seller. Any price that could be quoted would have to be regarded as more or less nominal.

TRADE GOSSIP

A syndicate of Toronto and American capitalists have secured a large tract of property in Toronto which lies east of Coxwell Ave. This land has a frontage of between 4,000 and 5,000 ft., and is said to have cost about $125,000.

The intention is to build about 150 moderately priced homes, and as soon as arrangements can be made with the proper authorities, 20 or 30 houses will be started. According to present plans the houses will cost from $4,000 to $5,000, and the new homes will be surrounded with sufficient land to make them desirable. The remainder of the 150 homes will be built as the demand grows.

It is said that Hamilton intends spending $10,000 on the construction of asphalt pavement.

Plans have been prepared for a new theatre and office building in Halifax, N. S. Herbert R. Brewster, of Brooklyn, is the architect, while the building itself is for J. M. Franklin, Strand Theatre, Halifax. Tenders will be called for in the near future.

Plans for an addition to the New System Laundry Co., Elizabeth St., Toronto, are about completed. The proposed cost will be around $10,000.

Tenders will be received until July 25th, by J. W. Pugsley, sec. Dept. Railways and Canals, Dom. Govt., Ottawa, for section 1 and 2 combined Welland Ship Canal. The plans are at the office of the Chief Engineer of Dept. Railways and Canals, Ottawa, and office of Engineer in charge, Welland Ship Canal, St. Catharines, Ont. An accepted cheque for $700,000 is required.

One of the most recent enterprises to become established in Walkerville, Ont., is that of R. H. Cunningham & Co. This concern are specializing in industrial electrical furnaces, covering a wide range in heat treating. Mr. Cunningham, who was formerly with the Hiram Walker Metal Products, Ltd., states that electricity is becoming more extensively applied to the requirements of the various industries.

Hi-Speed Tools, Ltd., Galt, Ont, manufacturers of taps, dies, and specials in small tools, have recently appointed as their representatives, W. Bruce Campbell, Confederation Life Bldg., Winnipeg, for jobbers only in Winnipeg and the West; and Price & Campbell, 444 Main St. E., Hamilton, for Hamilton and Niagara Peninsula section, covering both jobbers and consumers.

The Philips Gies Foundry, Kitchener, Ont., are placing a number of specialties on the market, among the most important at present being "Superior" shaking and dumping grates, adaptable to any style of boiler, also a full line of water service boxes.

PERSONAL

William Washington Wylie, one of the pioneers of electric car manufacture, died at Ottawa recently. For nearly a quarter of a century the deceased was head of the Ottawa Car Mfg. Co. Mr. Wylie came to Canada about 40 years ago, and it was under his direction that the Ottawa Car Mfg. Co. reached its present day proportions.

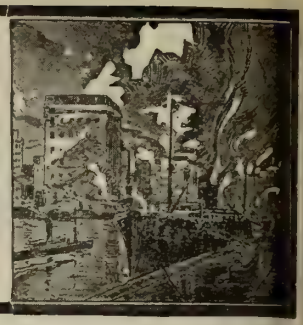
FUSING POINT.

Determinations of the fusing point of ncrete have been made at the Ameri- n Bureau of Standards on small speci- ens. They were found to have a fus g temperature of approximately 200° F., but the temperature probably ries with the kind of sand and cement ed. Fusion of concrete has been ob- rved in one or two very hot fires in inforced-concrete manufacturing ildings, and was also noticed in the e tests on columns recently completed the American Underwriters' labora- ries.

NEW DEPTH GAUGE.

The Brown & Sharpe Mfg. Co., Provi- nce, R. I., have developed a new mi- ometer depth gauge, to be know at No. 7. This gauge is said to be primarily portant because of its simplicity and acticability. It is furnished complete th three measuring rods and enables adings from 0 to 3" to be obtained thousandths of an inch, he micro- ter screw having a movement of 1". The desired rod is easily and simply placed in position by a cap, which permits the rod in the gauge to be withdrawn and the one desired inserted. Replacing the cap brings the shoulder on the rod against a finished seat. The shoulders on the rods are adjustable and permit individual adjustment of any rod. The tool is obtainable with either a 2½" or 4" base. The same adjustment for wear on the threads is used as that on their regular line of Micrometer Calipers. This tool is not shown in the Brown & Sharpe Small Tool Catalogue, but separate pamphlet, describing the tool, is obtainable from the company.



ARC WELDING ALUMINUM.

In a paper read before the Liverpool Sub-centre of the North-Western Centre of the Institution of Electrical Engineers, Mr. F. J. Heyes—Metropolitan-Vickers Electrical Company, Limited—stated that he had attempted the arc welding of aluminium, using the ordinary acetylene welding fluxes, without any success whatsoever, and he reached the conclusion that it is essential to use a flux which is not easily vaporized. For this purpose he found cryolite suitable. Cryolite alone was no use for oxy- acetylene, as in that process the aluminium was only heated up to the melting point of the metal, and as the cryolite was only viscous at that temperature it would not allow the molten metal surfaces to come together, and no weld could be made. On theother hand. in arc welding, a small pool of molten aluminium was formed at the point being welded, the temperature of which was far above the melting point of the metal, some ofthe aluminium being deposited in the form of vapor. At thot temperature the cryolite became quite fluid and ran freely on the surface, enabling a very good weld to be made. In trying to weld with a plain electrode the aluminium hung in globules at the end of the electrode, and there was still a tendency for this to occur when using cryolite alone. A small percentage of chloride, however, overcame that difficulty, and rendered welding much easier. In acetylene welding it was advisable to use a rod of aluminium containing the flux.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

BELIEVES BRITAIN WILL SOON REGAIN HER HOLD ON WORLD'S MARKETS

"NOW that the coal strike is settled, we may expect the British manufacturer to return to his former position in the world's markets." This is the opinion of F. W. Field, British Trade Commissioner in Ontario. He goes on to say that there is an increasing use of oil for steam arising and power purposes generally. Compared with coal, however, its use is of such relatively limited extent that it has no very material bearing upon the main position, and before industry could look forward to a period of progress the coal dispute had to be settled upon a more or less stable basis. The production of ample supplies of coal and its sale at lower prices is of such paramount importance that, while a settlement of a temporary character would have been welcomed by a portion of the community, the majority felt that our industries must be safeguarded, as far as possible, against an early recurrence of such a disastrous dispute, and that it was not sufficient to aim at peace at any price.

"Our manufacturers are again beginning to quote attractive prices in the Canadian market. A Birmingham firm, for example, submitted a price to a Toronto buyer last week which was well under the best foreign price received. The process of regaining our trade may be a little slow, but I have no hesitation in saying that the British manufacturers will continue to compete keenly with foreign countries, and will regain much of their former trade, which was lost during their great efforts to win the war. The Old Land and the Dominions will also build up a substantial volume of inter-Empire trade during the next few years. In this business Canada will be a very important factor, both as buyer and seller.

"An analysis of British trade satistics for the first quarter of this year shows some interesting changes in the direction of trade. By grouping the countries into European, the U. S. A., other foreign, and British possessions, it is seen that, owing rather to a decrease in exports than to larger imports, the excess of exports over imports with the European countries has fallen from approximately £76,000,000 in the first three months of 1920 to a little over £3,500,000 in 1921, which compares with an adverse balance of £16,000,000 in 1913. With U. S. A., the excess of imports over exports was £24,600,000 in 1913. £111,900,000 in 1920, and £67,200,000 in 1921, while, in the remaining two cases (other foreign and British possessions), adverse balances in 1920 of £22,900,000, and £71,100,000, have been converted into favorable balances of £3,400,000 and £7,200,000 respectively."

FUTURE IMPORT TRADE OF POLAND

Conditions Must Become More Normal Before Trade is Likely to Increase. German Competition Feared. Goods Must be Adapted to Suit Local Requirements.

"The import trade is not likely to increase until conditions become more normal, the currency appreciates, and the buying power of the country is larger." So states a writer in the British Board of Trade Journal, speaking on the future import trade of Poland. He goes on to say that it is readily admitted that Poland will become a buyer of foreign goods in the future not only for her own needs but as a middleman for the Russian market. The Poles have an extensive and accurate knowledge of Russia and should play an important part in the commercial and industrial regeneration of that country. German competition is likely to be very keen in this part of the world, as, having lost important colonial markets, she will probably devote special attention to the capturing of Polish trade. It is therefore essential not to consider the Polish market as a buyer of goods to be utilized only in Poland—the scope is much larger.

German and other competition was not felt much during 1920; this, as regards Germany, was perhaps due to the enforcement of special regulations by which the export from Germany to Poland of a large number of articles was prohibited by law, but such goods as have been offered are cheaper than British-made goods.

With a view to competing successfully, it will be necessary for British and other traders, in the first instance, to adapt their goods to local requirements, to appoint local representatives of a good standing with a thorough knowledge of the country, and to sell goods on credit, as soon as local conditions will justify the granting of it. In some branches it will be indispensable to keep stocks of goods in Poland to enable quick delivery with a view to overcoming the advantage which Germany, Czecho-Slovakia, or Austria possess, owing to their more favorable geographical position.

ORDERS EXPECTED FROM RAILROADS

It is expected that railroads will i the near future release orders of fai proportions for repair work materia such as steel plates, sheets, angle bolts, nuts, channels, spikes, smal beams, bars, rods, etc., etc.

Speaking on the subject, W. A. Bald win, manager of the Ohio region of th Erie Railroad, says some roads are plan ning to place tonnage for car and loco motive material. Such business wi probably be let as soon as the carrier ascertain the results of reduced wag payments. Cars used in the grain trad are badly in need of repairs and man box cars have defective roofs whic must be repaired before they can b used.

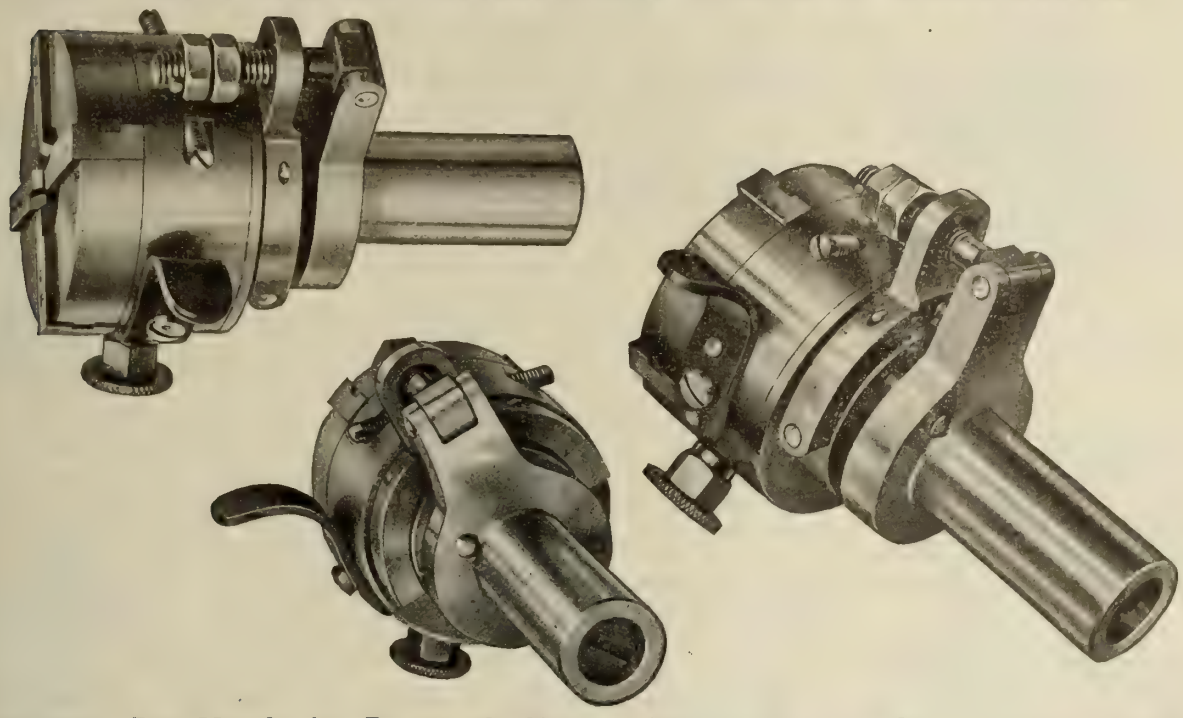
Steel makers state that the bank are prepared to deal liberally with th roads in the matter of furnishing mone to repair cars, especially for movin crops.

INCREASE IN PARCEL POST RATE

The recent increase of rates on pa cels is, according to the United Kin dom authorities, due to the heavy i creases of cost of handling and conve ance. As a consequence parcel po rates to the United Kingdom on an after July 1st will be 20 cents for th first pound, and 16 cents for each su ceeding pound or fraction thereof.

Below is shown in table form th rates existing at present on parce from 1 to 11 pounds.

1 lb	20 cen
2 lbs	36 cen
3 lbs	52 cen
4 lbs	68 cen
5 lbs	$0
6 lbs	1
7 lbs	1
8 lbs	1
9 lbs	1
10 lbs	1
11 lbs	1



GOING DOWN.

A survey of the labor situation Canada for the month of May, 1921, more encouraging than for some tir past, and warrants optimism for the i mediate future. The review discloses further decline in the cost of living, illustrated in the cost of a weekly fa ily budget of staple goods, and a ge eral improvement in wholesale and r tail trade throughout the Dominic There was an increase in the volume employment, activity being especia noticeable in building construction, t value of permits taken out being nea double of that of the month of March.

The Geometric Tool Company **New Haven, Connecticut, U.S.A.**

Right on the Lead

A NEW HIGH MARK IN SCREW CUTTING

Geometric Die Heads for Brown & Sharpe Automatics and Other Single Spindles

THE New Style DS Geometric Self-Opening and Adjustable Die Heads were designed primarily for the Brown & Sharpe Automatic Screw Machines. They are quite as well adapted to other Automatics, and where they are used, there is no reversing of the spindle to back the Die Head off the threaded work.

These Die Heads are simple and compact. They do not depend on the turret feed, but float to suit the thread being cut. This prevents stripping and shaving of the threads and makes the usual close camming of the machine unnecessary.

Note the lever trip, which reduces the force of tripping the Die Head and lightens accordingly the reaction on the threads being cut.

Buffer Springs allow the Die Head to yield slightly when the Chasers come in contact with the work, insuring a good smooth thread from the start.

The two check nuts at the side of the Die Head provide easy adjustment of the point of tripping.

Shock and wear are eliminated by the spring closing attachment. This is of special value when closing the Die Head rapidly.

Push Buttons eliminate all trouble in inserting the Chasers.

No face plate is necessary, making it possible to use projecting Chasers where required for cutting close to a shoulder.

The Closing Attachment is located in a convenient position to strike a stop on the machine, which automatically closes the Die Head when the turret revolves.

The Chasers are of sturdy construction. They have long bearings in the Die Head skeleton and are supported by hardened keys, which prevent tilting and consequent cutting of taper threads. There are four Chasers in each size Die Head.

The Die Heads are provided with shanks to fit the particular size machine on which they are to be used.

Consider the economy of using one of these Die Heads with its Micrometer Adjustment, over a button die, which has no adjustment.

Geometric Die Heads are sent out on trial to reliable concerns.

NEW SYSTEM OF WIRED WIRELESS PHONE SOON TO BE IN OPERATION

WHAT is said to be the first commercial installation of wired wireless in Canada is soon to be in operation between Edmonton and Calgary. The inauguration of this system is a new step in telephony in Canada, although the carrier sysem of telephony, as well as telegraphy, has been used quite extensively in the United States for the past two or three years.

The system will provide two additional telephone circuits between the two cities by superimposing high frequency currents on open wire lines which are now used for toll service, thus avoiding the necessity of stringing additional wire lines. For the benefit of those who are not familiar with the operation of carrier systems, it may be stated that multiplex operation is obtained by the use of carrier currents of relatively high frequency, with which the voice currents are combined. The voice curent for each conversation combines with or modulates a carrier current of a definite frequency which carries it over the open wire line to the distant station. The combined currents for a number of conversations are transmitted over the same wire, but at the distant end they are separated so that each conversation goes to the proper person.

Additional Toll Service.

The application of carrier systems to toll lines will not interfere with the ordinary use of the wires for telephone and telegraph purposes, but will provide additional toll circuits which will accommodate telephone traffic in the same way as ordinary circuits. The additional circuits provided by this means will transmit the characteristics of the voice with the same degree of clearness as ordinary circuits.

The Province of Alberta will, by the use of these carrier circuits, be able to extend its range of telephone communication to more remote points of the province than is possible at the present time. This is made possible by the fact that the transmission between Edmonton and Calgary will be somewhat louder by the carrier method than over the wire circuits as at present, and consequently the voice can be transmitted over longer circuits before becoming too feeble to be understood.

The Northern Electric Company Limited, who are furnishing this equipment, have been for some time past studying the adaptability of this system to the Canadian field and although they have not yet finished their studies, they say that the present indications are that, due to thickly settled yet widely separated areas, this means of communication is ideal to the needs. It may, therefore, be expected that other installations of this character will follow shortly.

HAMILTON SECURES NEW INDUSTRY

Hamilton has secured several additional industries, among them being the National Slag Products Co., which will utilize slag from the Steel Co. of Canada.

The officials of the new company have leased property on the C.N.R. and the beach line of the G.T.R. The company is capitalized at $300,000 and is headed by Edwin J Robertson, son of Senator Gideon Robertson.

VARIED ACTIVITIES IN WINDSOR PLANT

Windsor has a new industry in the Fournier Manufacturing Co., Ltd. This concern have a plant with floor space of 6,500 sq. ft., and are fully equipped with machinery, this including a large electro-plating establishment. They employ between 25 to 50 workers, are capitalized at $50,000 and have the following officers: R. M. Fournier, Windsor, president; S. J. Webster, Detroit, vice-president; N. F. Wray, Windsor, secretary; C. B. Smyth, Detroit, treasurer, and Col. E. S. Wigle, Windsor, solicitor.

This concern intend going into large production plating work, using their up-to-date equipment which is at present in thorough-going shape. They also manufacture the "Ideal" gas water-heater in two types, the cast iron disc for natural gas, and the copper coil for manufactured gas. Along with this line they are going to make a number of traps and other plumbing supplies. They are also taking a certain amount of production machine work from the automobile plants and other industries in the vicinity.

IRON IMPORTS FOR PAST TWELVE MONTHS

During the 12 months ending March, 1919, Canada imported iron and its products to a total value of $192,527,377, of which $185,116,309 represented the value of products of United States origin. During the next 12 months the total imports were valued at $186,319,876, of which $178,661,606 was spent for United States products. In each of the two years the value of iron and its products imported from the United Kingdom amounted to slightly more than $6,000,000. During the 12 months ending March, 1921, Canada imported iron and steel products from the United Kingdom valued at $16,698,085; $226,862,465 from the United States, and $2,065,903 from other countries, making a total of $245,625,453. Imports of iron and steel products for the year ending March, 1921, show an increase in value of 32 per cent. over the previous year and 22 per cent. over the valuation credited to the year ending March, 1919.

GERMAN COMPETITION VERY LOW PRICES

Inquiries instituted in iron and steel circles reveal a good deal of anxiety regarding Germany's threatened policy of price cutting as soon as there is exhibited the first sign of a trade revival in the United Kingdom.

J. E. Ray, trade commissioner at Manchester, says that already prices have been quoted on gas tubes nearly 50 per cent. below the quotations of British manufacturers. It is well-known that Great Britain found Germany in prewar days a most formidable competitor in foreign markets in connection with finished tubes of various kinds. Similar competition is again asserting itself, and it is feared that British producers, now seriously handicapped by greatly enhanced costs of production, will find the old rivalry in international markets resumed with added zest, while they on their part will be less fitted to challenge their German competitors.

Quotations are being received by some firms in the midland counties of England for steel billets, delivered, at $38.93 per ton 2,240 pounds; finished steel bars $51.10per ton, and gas strip at $60.83 per ton.

Not only are British makers unable to approach these prices, but even the French and Belgian producers are in some cases outquoted. If these German quotations are inclusive of import duty, and such is believed to be the case, the low prices become all the more remarkable.

PRESENTS ASSOCIATION CARLOAD OF MACHINERY

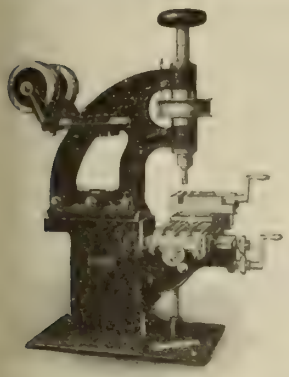
H. W. Petrie, Sen., of the H. W. Petrie Co., Toronto, performed a very useful service when he presented to the International Grenfell Association a carload of machinery for the industrial department of St. Anthony.

The machinery includes a ten-inch, four-sided moulder, a wood frame sticker, countershaft and parts, a portable forge anvil and blacksmith tools, a hacksaw, knife-grinder and shaper pulleys, belting and extra parts.

The Dept. of Marine will land the machinery at St. Anthony free of charge, so that in this way the Association will receive some very necessary and useful equipment at no cost.

OWEN SOUND PLANT WORKING FULL BLAST

According to a recent report, the Aluminum Steel Products, Ltd., Owen Sound, are operating to capacity. The plant is working full time, and is turning out various sizes of castings from the small brush holder in an automobile generator to the nozzles of vacuum sweepers. These brush holders are small but require to be very perfectly made and with the die casting machine the proportion that is spoiled is very small, almost negligible. They are said to be about 17% harder than the same class of goods made in sand moulds, are perfectly true and require practically no finishing.



MOVING A TOWN.

They are going to move the entire town of American Falls, Idaho, with its population of 2,000, two or three miles to a new site higher than its present location.

This work is to be attempted within a few months by engineers working on a huge irrigation project involving the impounding of the water of the Snake River by a dam a mile long and 60 ft high.

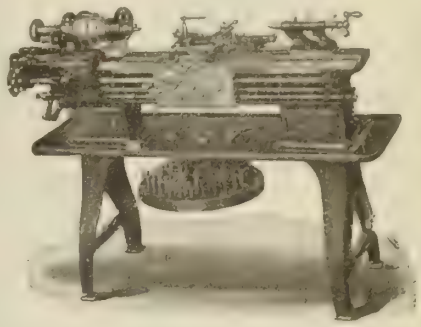
A "Keep Cool" Suggestion

With the thermometer determined to remain at the lofty heights of around 90 degrees, the workman toiling away at an old troublesome machine deserves your keenest sympathy. Perhaps if your job happens to be at a desk near an open window you are apt to forget that for every inefficient machine causing extra effort and extra motions production is dropping behind.



If you have one or two of these out of date "sweat boxes" why not get rid of them now—before they cost you more money. We can supply you with new motion-saving equipment that will get your work out on time and at least expense. Prompt deliveries; excellent shipping facilities.

COMBINATION GRINDER

The Grand Rapids Machine Co., Grand Rapids, Mich., has placed on the market a new machine said to combine the advantages of both thin drill grinder and tap grinder. This combination machine is made in two styles of two sizes each, and diamond wheel trueing mechanism, with diamond is standard equipment on all such machines. The drill grinding side of the machine is equipped with holder stop, which working in connection with the base of the diamond trueing device automatically places the drill holder in the proper relationship with the face of the grinding wheel.

ARC WELDING

Continued from page 33

welding with steel, and to remove the entire hardness of the entire section when welding with cast iron, the following procedure must be gone through. Where the piece is of such shape that it can be welded cold, reheating and annealing will make it machinable, i.e., any time after welding bring the weld and adjacent cast iron up to a little better than red heat and allow it to remain there from two to ten minutes depending on the size of the piece, then cool slowly by burying in warm sand, fireclay or limestone.

Where piece is of such shape that the cooling strains when welding quickly, as in electric welding, would warp or break the piece, preheating is necessary, but only to a small degree, i.e., less than red heat, in order to save the piece from breaking while welding. Directly after welding, bring the weld and adjacent cast iron up to better than red heat and anneal as before. This method results in either steel or cast-iron electrode applied to cast-iron being entirely machinable, and in the case of cast-iron electrode results in a weld which is not discernible from the original cast iron by either physical or chemical analysis.

In general, cast-iron containing small amounts of steel, i.e., so-called semi-cast iron, is much easier to weld than pure cast iron. Generally, the only welding done on cast iron, except in the case of accidents, is where the original cast iron is defective because of sand holes, porous spots or other troubles in casting: this slag must be entirely removed before satisfactory welding can be expected.

Usually the cast-iron electrode, while it becomes more fluid than steel under the arc, cools quicker than steel and from the outside inwards, because steel cools by the conduction of the heat in weld into the adjacent metal from the inside outwards, and hence with cast iron there is more chance of voids and gas bubbles being left in the weld and some sort of flux to prevent this is necessary in depositing cast iron. Desirable ingredients in such flux being:—

1. Quieting reagent. 2. Quick floater of dross to the surface. 3. Oxygen and nitrogen protector, so that bubbles, films or needles of oxide and nitride are not left in the weld. 4. Protection against rapid cooling of surface.

Such a flux is furnished with our electrodes beside especial care being taken that the C I welding rod is homogeneous and flows evenly through the arc.

Generally, careful spreading is the successful method to apply cast-iron electrode to cast iron; with steel electrode on cast iron, careful beading at the start and careful spreading as a finish.

The method of studding cast iron to give increased reliability and strength was developed by Mr. Joseph McAllister, of the N. Y. Central Railway, U.S.A., and under his direction was successfully applied to the maliciously broken cast-iron cylinders and other parts of the interned German ships in N. Y. Harbor, using the plant and resources of both the Erie and New York Central Railways.

AIR BLOWER

The New Jersey Motor Co., Plainfield, N. J., have developed a small blower which is said to transform a small volume of high pressure air into a large volume of low pressure air, this being used for the operation of rivet forges, and similar machines. A comparatively small amount of air is utilized through the compressed air line, as the greater portion of its air is drawn from the outside.

VERTICAL BULLDOZER

A vertical bulldozer, especially adapted for railroad steel car construction and repair work has recently been developed by the Beatty Machine & Mfg. Co., Hammond, Ind. This type of bulldozer is for the pressing and forming of such parts as stakes, sills, diaphragms, etc. Various sizes are built, up to a machine with 500 tons ram pressure.

COOLANT PUMPS

The Alemite Die Casting & Mfg. Co., Chicago, Ill., have developed a line of coolant pumps. These are made in five sizes with capacities ranging from ½ to 10 gallons per minute, when run at their rated speed of 300 r.p.m. The pumps have only four moving parts.

SQUARING SHEAR

The Niagara Machine & Tool Works, Buffalo, N. Y., have added to their line of shear a new machine to be known as the No. 8-H squaring shear. This machine is equipped with a set of gauges that insures the accurate squaring of sheets, thus making possible their convenient handling and welding. The cross-head is of a heavy box construction, is guided in liberally proportioned ways, and is counterbalanced. The main shaft and eccentrics are forged in one piece of a tough grade of steel. The clutch block is equipped with removable hardened and ground striking jaws, as well as with hardened backlash jaws. The clutch wheel also has removable hardened and ground striking faces and a backlash pin. Two center bearings are supplied for the main shaft, and these are placed as close as possible to the eccentric and hold-down cams, so as to obtain the maximum support.

The hold-down cams bear against hardened steel rollers which are lubricated through hollow pins, and the hold-down rods are provided with springs to compensate for various thicknesses of plates. Self-adjusting brakes lined with asbestos are supplied, these brakes being made in hinged halves and equipped with automatic springs which com-

ensate for wear. The knife chuck is ovided with pockets that enable the ife bolts to be easily removed from e top. The chuck has T-slots on top accommodate gauges, and on the ont for gauge brackets. A screw and t-screw on each end of the knife uck facilitate adjustments of this ember. The housings are of massive nstruction and do not require stay-ds for cutting to the maximum ca-city; however, stay-rods and stay-rod gs are supplied if desired.

The counterbalance weights are below e floor line to comply with the safety des of some sections of the country, d the capacity of this machine is mild eel up to 5/8 in. thickness. The ma-ine's nominal cutting length is 8 ft., d 30 H.P. is the power necessary to ive it.

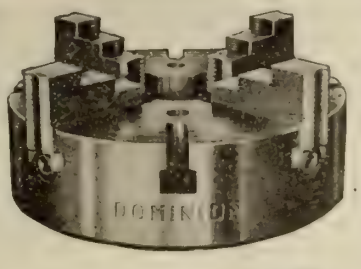
MOTOR DRIVES.

C. C. Bradley & Son, Inc., Syracuse, ve developed a line of motor drives lapted for use on their particular style hammers. These motors are made r alternating or direct current and n be supplied in various voltages, ases, and cycles.

HARDNESS TESTING MACHINE.

The Alfred Herbert, Ltd., Coventry, ngland, with Canadian offices at 1-3 rvis St., Toronto, Canada, have placed the market a patent power operated rdness testing machine, which oper-es on the Brinell principle and uses 10 mm. ball. It employs the standard essures of 3,000 or 500 kg. as requir-d according to the character of the ma-rial to be tested. The outstanding atures of the machine are said to be: wer operation; pressure automatically plied; period of application or pres-re is absolutely uniform; no strain on perator; high output; accurate results; bust construction and suitable for orkshop use on production. Its lead-g principle is that it is a power-oper-ted machine by which the time re-uired to apply the load, the duration f the load and the time taken to re-ove the load are uniform for all tests nd do not depend on the personal equa-on of the operator or on his physical ffort. The operation of the machine by ower, enables the attendant, who may ven be a boy or a girl, to make tests ntinuously without fatigue and with-ut chance of error.

Apart from the main frame, which arries all the mechanism, the machine ay be said to consist of two elements, weighing element and a straining ele-ent.



The ball through which the pressure applied to the specimen is carried by e lower end of a vertically moving lunger, the weight of which is neutral-ed by a light spring. This plunger oves upwards a small amount when e specimen to be tested is raised into ontact with the ball, the pressure be-ween the specimen and the ball being eighed by a pair of compound levers nd a weight which becomes poised hen the full pressure is reached.

The Straining Element.

The object to be tested is placed upon flat anvil or pressure plate resting on spherical seat on the top of a vertical crew which can be elevated by a hand heel to bring the work into contact ith the ball. The spherical seat has a ecess in the centre so that a vee block r any special form of support required or cylindrical or other work may have a projection which will locate it without risk of slipping.

The screw itself occupies an axial positon in a vertically moving cylindrical ram, the small upward movement of which forces the work against the ball and applies the pressure which is regulated and resisted by the poised weight of the weighing element. The lower end of the ram carries a roller which rests on a cam which makes a single rotation for each test. The cam is formed so as to apply the load gradually, to maintain it for the predetermined period and then to remove it.

The cam is rotated by a wormwheel and worm driven by spiral gears from a single driving pulley near the base of the machine. The motion is engaged by depressing a pedal and is automatically disengaged at the end of one revolution of the cam.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

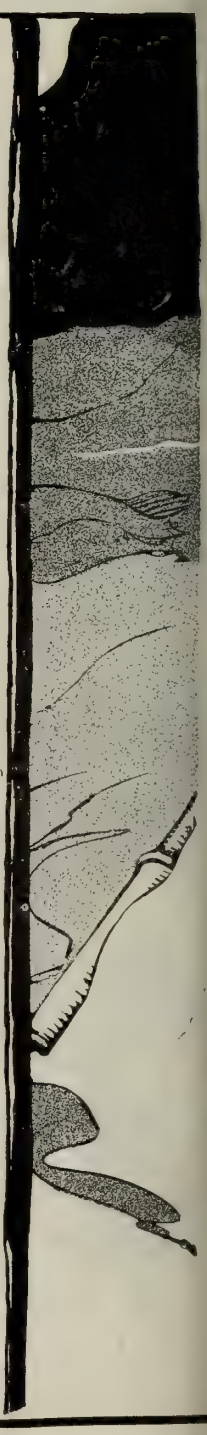
You Can't Row a Boat with One Oar

An unbalanced advertising campaign, like a one-oar boat, never gets anywhere.

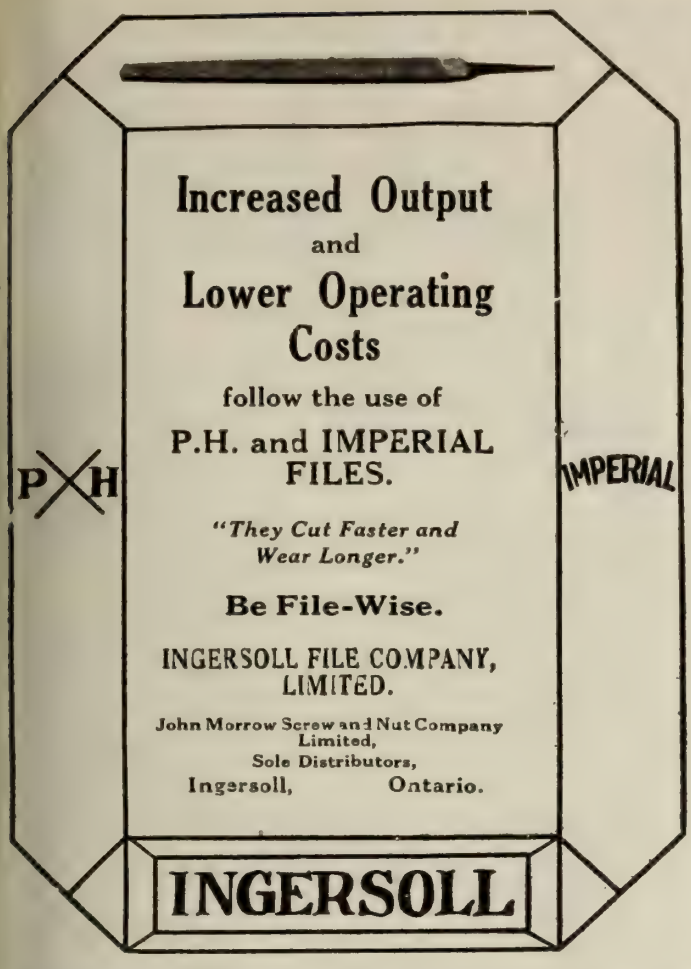
Sound copy must be balanced by scientific space selection. Mediums deserve as much attention as merchandising.



To buy space scientifically circulation must be *analyzed*—not merely counted.

Do you ask of a publication not only "How much?" but also "How did you get it?" and "Where does it go?" If you fail in these particulars you are trying to make an advertising campaign go with only one oar.

The answers to these questions can be obtained by studying the A. B. C. reports. To read the circulation figures only is not enough, even though they are verified by the A. B. C. audit. This is but the beginning.



Advertising is being put to a test to-day, which it can meet if you put circulation to the test of A. B. C. reports.

Canadian Machinery is a member of The Audit Bureau of Circulations.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

LANDIS

No. 4A SPECIAL GRINDING MACHINE

This Landis Grinding Machine can perform all the operations necessary to put the gasoline motor in first-class condition and repaired as good as new. The installation of one machine in your shop is not limited to work of any special nature, it is designed to handle any grinding operation connected with the repairing of automobile, truck, tractor and other gasoline engine parts.

Let us show you what Landis Machines can do for you. Write to-day for literature.

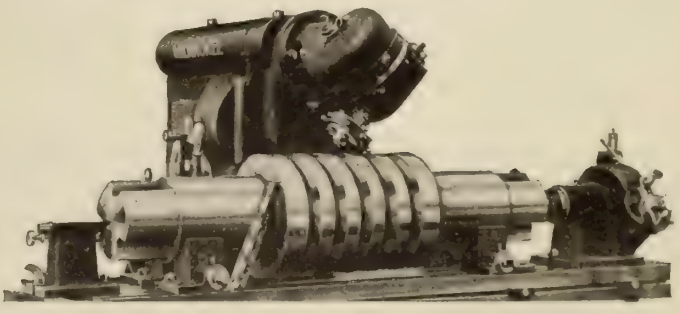
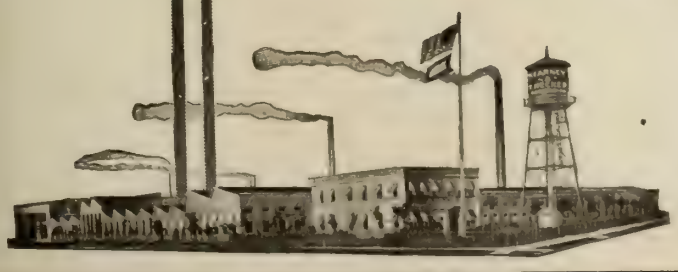
MILWAUKEE MILLING MACHINES



Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

OPERATED IN CONJUNCTION WITH A CONTINENT WIDE NET-WORK OF DISTRIBUTION STATIONS

"Liquid Air" Oxygen Means a Saving in Transportation

With a network of Factories, not only planned but in actual operation, and a number of Distribution Stations situated at all large centres all over Canada, Purchasers of Oxygen can obtain their supplies at a point very near to the point of consumption. This completely obviates heavy freight charges on cylinders and assures an immediate supply at any time within a few hours and even minutes after the orders are placed.

All cylinders conform to the specifications of the Canadian Railroad Board and are made to ensure safety without unnecessary weight. When purchasing "Liquid Air" Oxygen you not only save on freight, but in very many cases this expense is almost elimina[illegible]

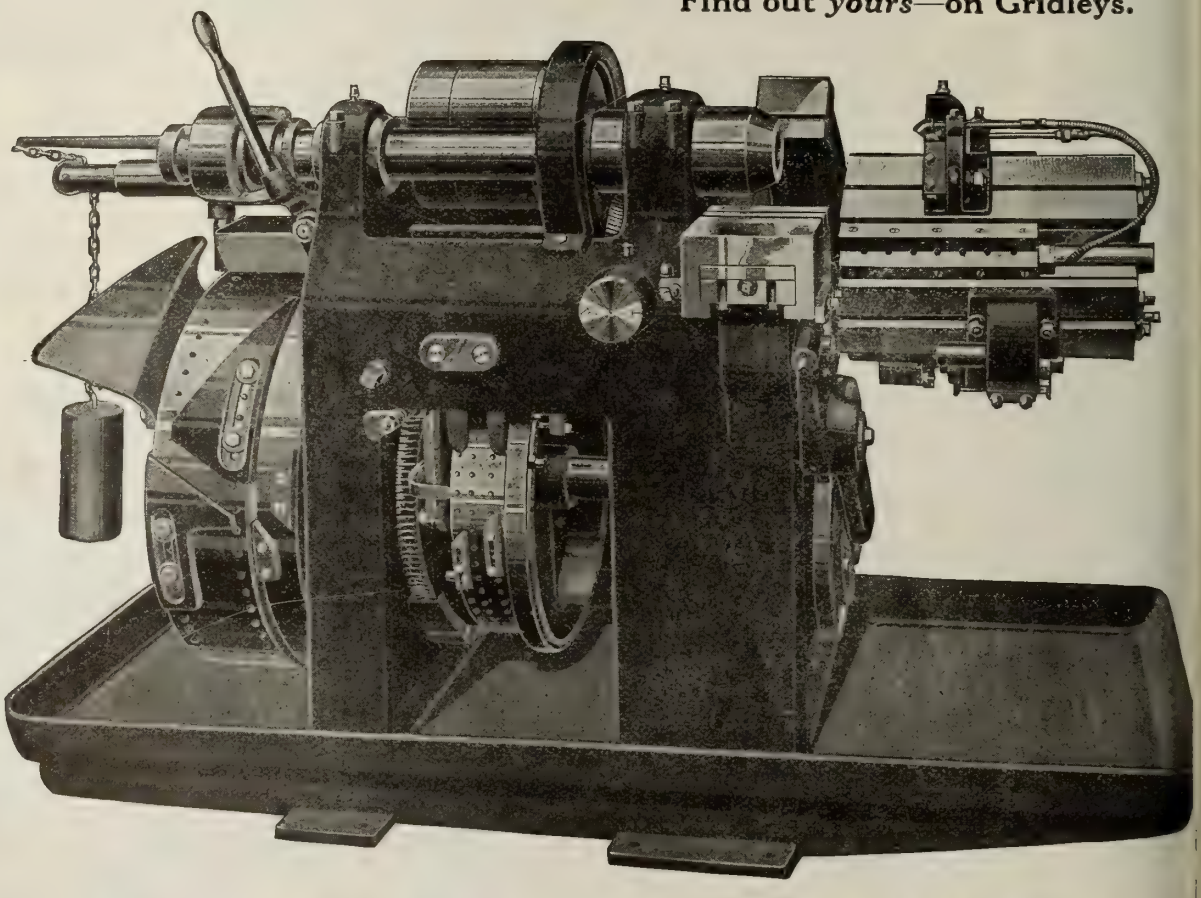
Pushing the Heavy Turning on GRIDLEY AUTOMATICS

Speed of output and accuracy are some times strange bedfellows.

With accuracy constantly in the fore ground Gridley Automatic Turre Lathes are constructed to be pushed i the long or heavy cut and to stand u under continuous running.



After all, turret lathe efficiency is lo per piece cost, and low costs mean simpl getting the maximum output per hou and accuracy as good as you want it.

Find out *yours*—on Gridleys.

THE OLD-TIMER SPEAKS

"You youngsters brag about your Starrett Tools—but there isn't one of you today any more proud of his Starrett kit than we old-timers were forty years ago.

"Times change. There's more machine shops now—and larger ones. There's more tools in the Starrett line—and better ones. But there's one thing, I notice, that's just the same now as forty years ago—the respect and preference—the pride of ownership—that Starrett Tools inspire in good machinists." Get Catalog No. 22-3

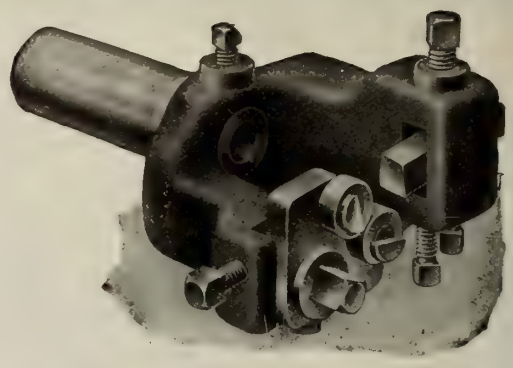
"M.D. Elk"
"Rotex"
"Elk Dust"
"Keystone Dust"
"Rotex Dust"

Elk Service Means Lower Costs



There are two important things to consider in buying firebrick—**price and quality.** When you buy ELK BRAND FIREBRICK we take a keen, unprejudicial interest in seeing that you get the class of firebrick you need. If a moderate-priced brick fills the bill we never recommend a brick of higher quality at higher price.

We make bricks in all standard sizes and shapes.

Elk Brands Firebrick are reliable. Specify them in your next order.

WILLIAMS' "AGRIPPA" TOOL HOLDERS

When your work demands unusually heavy cuts, when the piece in process is particularly difficult to turn, when you hit hard spots, or when speed in production is required, you can depend upon Williams' "Agrippa" Tool Holders, "The Holders that Hold."

Made in a wide range of sizes for all regular machining operations—Turning, Boring, Planing, Threading, Knurling, Cutting-off and Side Work.

Ask your Dealer : Machinists' Tools Book on request.

United States Electric Drills and Grinders

The "BUZ"

For all kinds of general drilling in metal up to 5/16"—name plates, cotter pin holes, oil holes, etc.

The "BUZ" is especially adapted to corner drilling—drills within ¾" of corner. Switch is located in handle; under absolute control at all times. Attaches to any lamp socket, alternating or direct current, 110 or 220 volts. Guaranteed the most powerful electric drill of its weight on the market.

Order a few to-day for trial. Their time and labor saving ability will convince you you need more!

For Sale By

CINCINNATI, OHIO

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself.

Write.

The Walton Co.

Hartford, Conn.

THE JOHNSON FRICTION CLUTCH

The Case Against the Countershaft

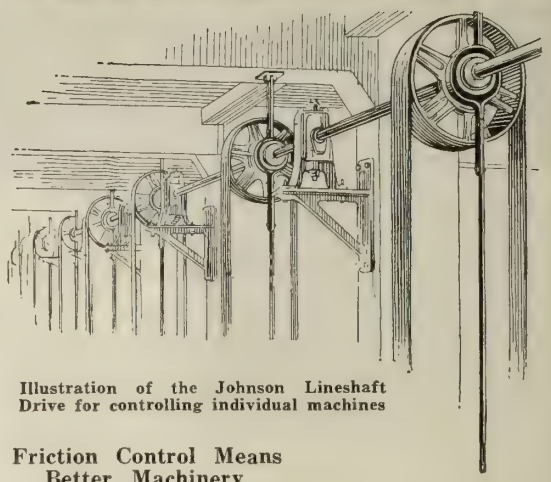
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.



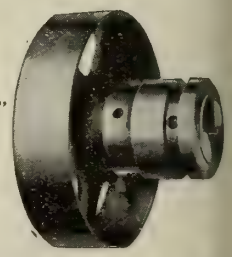


Illustration of the Johnson Lineshaft Drive for controlling individual machines

Friction Control Means Better Machinery

Whether it is applied overhead or in the machine itself.

Write for our Booklet "Clutches as Applied to Machine Building" and our Yellow Catalog.

Cab Tire Cable

The Cable De Luxe for Industrial Purposes

This advertisement illustrates:

A length of Northern Electric Cab Tire Cable
One Northern Electric No. 511 Marine Plug and Receptacle
One Northern Electric No. 300 Hand Portable

This combination is ideal for Industrial Portables. It is especially adapted for use in damp localities, or where gas or oil fumes abound, and where other types of cable would be subject to mechanical injury.

Because of its flexibility and durability, Cab Tire Cable is in a class by itself for industrial purposes, and the ever-increasing orders received from Machine Shops and Industrial Plants all over Canada prove its merit and popularity.

Our nearest house will give your inquiries immediate attention.

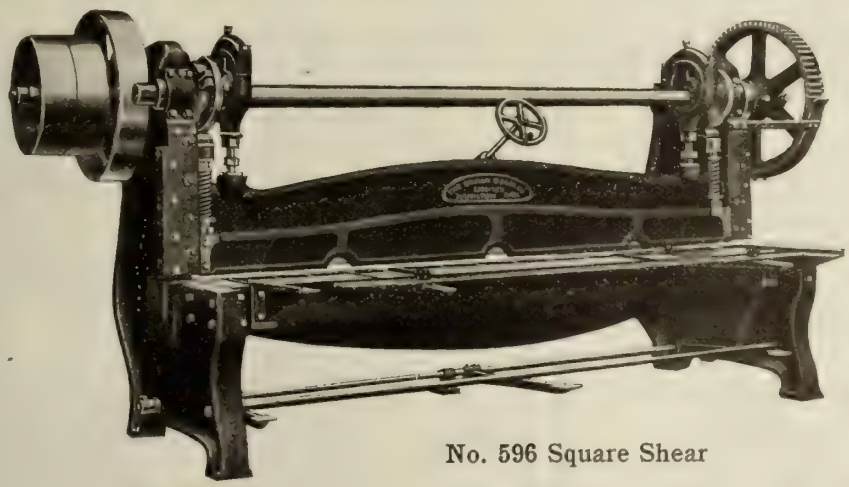
Do You Find Ordering Hard?

We mean ordering a new machine—intended as a labor-saver and production-spreader.



There was a time when it **was** necessary to send for sheafs of catalogues, spend hours of valuable time investigating and end up with a choice which was perhaps 90 per cent. guesswork.

Today things are different. It's a simple matter to order "B-B" tools. The "B-B" trade mark represents Sheet and Metal Workers' tools of proven worth plus an advisory and consulting service which is always at your command.

No. 215—Power Press

We are always ready to talk over your problems with you. If you wish advice consult us freely.

No. 596 Square Shear

A Complete Line of

Tinsmiths' tools and sheet metal working machines of all kinds; canners' and evaporators' machinery, shears of every description, power presses for punching, forming, embossing, blanking.

"ROYLITE"
CLEANER

Cleans All Metals

Made In Canada

Oil, Grease, Paint, Varnish, Enamel
All Quickly Disappear before "ROYLITE"

Ask any man who has ever used "Roylite" Cleaner, why he prefers it and this is what he'll tell you. "Roylite" is the fastest, most effective cleaner we have ever used. It lasts longer and costs less than any other.

Here's the reason "Roylite" is different to most cleaners. It emulsifies or lifts grease from the work and does not lose its strength in saponification like Caustic Soda, Lye, Soda Ash, etc. by creating a soap in the solution. This enables the use of both with less additions of this cleaner than others.

"Roylite" is easy to apply. All chemicals are soluble, quickly dissolve in water, and are ready for immediate use, "Roylite" is guaranteed not to discolor or tarnish the brightest surface.

HEALD

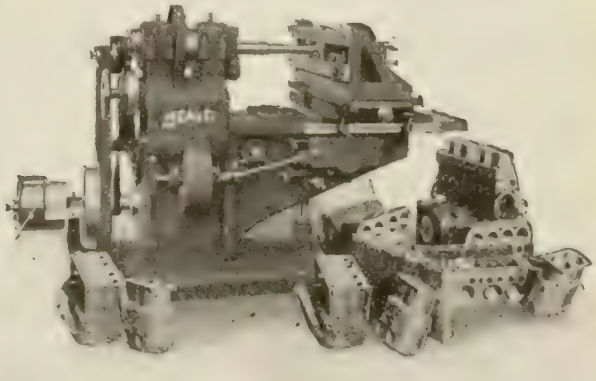
Cylinder Regrinding Profitable Business

PHOTO OF TRINDL MACHINE WORKS-CHICAGO-WHERE THERE ARE SIX HEALD MACHINES & FIFTY MEN WORKING DAY AND NIGHT REGRINDING CYLINDERS

How Many Cylinder Grinding Companies in Your Locality?

We venture to say very few, if any at all. When you know that a very handsome profit results from 3 four-en bloc cylinders a day and that 15 to 20 holes is the usual production, you begin to realize the possibilities of this field.

Without question there are more opportunities in cylinder regrinding and it is the most active of any similar proposition in Canada to-day.



It does not require a large amount of capital nor expensive equipment. Small machine shops, auto repair shops and welding concerns are particularly adapted to this work. They are equipped with lathes, drills, etc., so it only requires one or two additional machines to start in immediately on work, which is just lying around waiting to be picked up.

Let us get with you to-day personally or by mail and give you facts and figures on the profits and possibilities of this business.

We know of no one who has gone into this work with a fair amount of energy and business ability who has failed. We can refer you to any number of concerns who have started in on a shoe string and now have a prosperous and successful business.

Having convinced yourself of the possibilities of regrinding, there is but one method and one machine which will handle the work profitably and to best advantage. That is a Heald Style No. 55, built expressly for regrinding work. It is simple, moderately priced, self-contained and has a very large capacity and range, easily taking care of singles, doubles, fours and six en bloc cylinders.

Among the automobile manufacturers of pleasure cars, 84 per cent. grind and with commercial cars, 91 per cent. In all cases Heald machines are used exclusively.

All sizes are handled on the Heald Style No. 55

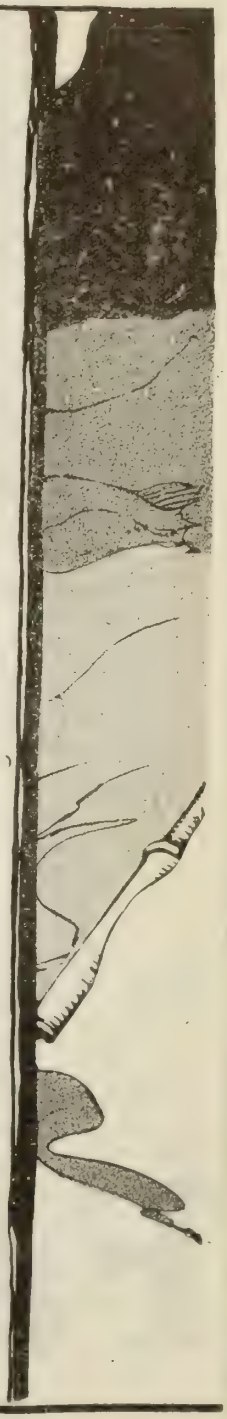
You Can't Row a Boat with One Oar

An unbalanced advertising campaign, like a one-oar boat, never gets anywhere.

Sound copy must be balanced by scientific space selection. Mediums deserve as much attention as merchandising.



To buy space scientifically circulation must be *analyzed*—not merely counted.

Do you ask of a publication not only "How much?" but also "How did you get it?" and "Where does it go?" If you fail in these particulars you are trying to make an advertising campaign go with only one oar.

The answers to these questions can be obtained by studying the A. B. C. reports. To read the circulation figures only is not enough, even though they are verified by the A. B. C. audit. This is but the beginning.

Advertising is being put to a test to-day, which it can meet if you put circulation to the test of A. B. C. reports.

Canadian Machinery is a member of The Audit Bureau of Circulations.

Design of Lathe, Planer, Shaper and Slotter Tools

The Factors Which Decide What Shape of Tool Will Prove Most Efficient for Any Given Cutting Operation—The Ideal Tool to Use For a Known Combination of Factors—Effect on Shape of Tools Due to Vibration

THE design, manufacture and use of lathe, planer, shaper and slotter tools is a subject for careful consideration in every large machine shop. The suggestions for making the most efficient forms of tools and for maintenance at least expense, as embodied in the following matter, are based upon years of thought and experimenting by men who have devoted their time exclusively to tool production.

Other discussion of the subject take it for granted that tool grinding and regrinding are lengthy and laborious operations. They therefore devote the greater part of their remarks to the question of tool forging, which is to be done in such a manner that subsequent grinding shall take as short a time as possible.

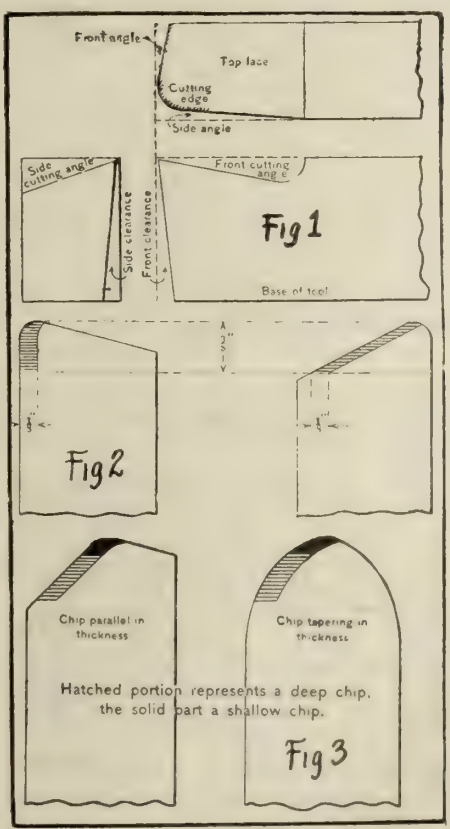
Forging is at best a rough and ready, inaccurate and inefficient process, and if without detriment to the tool, it can be largely eliminated, an important stage in progess towards efficiency is reached.

It is sometimes claimed that tools should be forged because the cutting properties of the steel are thereby improved. This may conceivably be the case with steels of poor quality, but is certainly not true of any recognized brands of high speed steel. On the contrary, there is always considerable risk that the steel will suffer through being worked at too low or too high a temperature. The hammering at heats outside of certain heat limits is most destructive to high speed steel.

By the method about to be discussed, the shaping of the tool is done in the majority of cases by grinding instead of forging. This grinding, which is done dry before hardening, has been proved to have no deleterious effect on the steel, nor is it conceivable how intelligent grinding could possibly cause any injury.

If, therefore, by means of grinding, a tool can be made to a definite predetermined shape in a fraction of the time required for forging the advantages should be investigated.

Tool Design.



If every lathe, planer, shaper and slotter operator were allowed to design or control the design of the tools he used, there would be such a multiplicity of tools in the shop that confusion would be inevitable, and the result would be inefficiency, reduced output, increased power charges and considerable waste of time.

It behooves those in authority therefore to tackle the tool problem in real earnest. The first item in the programme is to carefully consider the machines which use tools of the lathe type and the nature of the operations performed thereon. Using in the first place the experience of others, supplemented, when necessary, by experiments, those who desire to improve their tool system will soon realize the necessity of a set of standard tools applicable to every machine and every operation concerned. They will also see the desirability of making such a set of standard tools small, yet with enough flexibility to cover every requirement.

When the term "Standard Tool" is used, a tool of fixed and unalterable shape is not meant, because according to the nature of the operation on which it is to be used, two or three variables will enter into its makeup.

A standard tool is one with a standard profile, but the rake of the top face, the radius at the cutting point, the inclination of the cutting edge to the tool shank, and the clearances of the cutting sides should be varied to suit the machine, the material being machined, and the nature of the cut.

None of these variables, however, need affect our decision to lay down certain standards; they merely influence the question of flexibility in suiting the standards selected to the needs of the shop.

Figs. 1 to 3. Fig. 1. Terms used in defining shape of tool.
Fig. 2. Effect on the chip thickness when the cutting-edge is lengthened, while the depth of cut and rate of feed remain the same.
Fig. 3. The difference in the chip section cut by a straight-edged and a round-nosed tool.

Definition of Tool Parts.

Before proceeding further, it is desirable to define the terms used to designate the various parts of a tool. A tool consists of the shank and the nose. Unless otherwise stated the shank will be presumed to be rectangular. See Fig. 1.

Rake is the angle at which the top which bears against the support that takes the pressure of the cut. The top face is that which takes the friction of the chip as it is cut from the work.

Rake is the angle at which the top face is presented to the work. It is usually a combination of side cutting angle and front cutting angle, though it may in some cases consist of either of these separately. The profile is a plan view when looking at the top face from a point at right angles to the base. It is determined by the combination of the side and front angles and the radius of the cutting point.

Clearance is obtained by grinding away that part of the tool nose which would otherwise rub against the work during the cut. According to whether it is measured from the front or the side of the tool nose it is called front clearance or side clearance.

The radius of cutting point is the amount the corner between the front and side angles is rounded off. In determining a set of standard tools, Profile, Clearance and Rake must be considered.

Standard Profiles.

It is not often realized what an in-

Data published by courtesy of Alfred Herbert, Ltd., Coventry, England.

portant bearing the profile of a tool has on its efficiency as a cutting instrument. In Figure 2 is seen a representation of two tools performing the same work at the same depth of cut and at the same rate of feed.

The cross sectional area of the chip is the same in both cases, yet the one on the right is obviously a much thinner chip than the other. The cut being spread over a greater length of cutting edge, this tool will be therefore much more durable than the one on the left. On the other hand, if the tool on the left will stand up to the work imposed on the short length of cutting edge in action, it follows that, with the tool on the right, the rate of feed can be increased, until for an equal length of cutting edge the same cross sectional area of chip is being cut from the work. Suppose the length of cutting edge in the one case to be twice the length of the other, twice the amount of work can be done in the same time. The first rule, then, in selecting a tool profile is that:—The maximum length of cutting edge must be in action for any given depth of cut.

Whether the portion of cutting edge in action should be straight or curved depends somewhat on circumstances.

A straight-edged is easier to make than a round-nosed tool and deserves consideration accordingly. It also distributes the cut evenly over the cutting edge at any depth of cut.

A round-nosed tool has a certain advantage in that it lends itself to a greater variety of operations without material alteration. Where the depth of cut is constantly varying, as in turning a hammer forging, the cut is distributed over the cutting edge in a varying amount more proportional to the strength of the tool nose. The choice between the two is perhaps more one of preference than of efficiency.

A study of Fig. 4 reveals the fact that the chip from a straight-edged tool consists of a band of metal with straight serrations across it, while that from a round-nosed tool has curved serrations across it.

This would seem to point the moral that the metal in the chip is more distorted, therefore more power is consumed, when using a round-nosed tool than when using a straight-edged tool, for the following reasons.

Each portion of the width of the chip passes away from the cutting edge at right angles to a tangent at the point of cut. With a straight-edged tool the chip passes over the top face freely because the directions of motion of every portion of the chip are parallel to each other. With a round-nosed tool the extreme edges of the chip are, while passing across the cutting edge, running towards each other, therefore extra work is done in forcing the chip away from the cutting edge owing to the rubbing action that must take place between the particles of metal forming each chip section. It may therefore be assumed that in the main the preference would seem to lie with a tool having a straight cutting edge. Any advantage which the round-nosed tool may be considered to possess can easily be given to the straight-edged tool by grinding a large radius on the point.

So far is has been assumed that the metal to be cut is homogeneous. That this is not so every lathe hand knows. Frequently the cut must be taken just under a hard skin, which very soon destroys that part of the cutting edge against which it bears. Again the surface of the work may be scaly or gritty, which is equally as bad for the tool.

These things must influence choice of a suitable tool. It is logical to assume that the shorter the length of cutting-edge in contact with the skin, the less damage will be done to the tool and the easier it will be to repair what damage is done. The shortest distance through the skin is at right angles to the surface, therefore where the tool comes in contact with the skin, the cutting-edge should be as nearly as possible following that shortest distance.

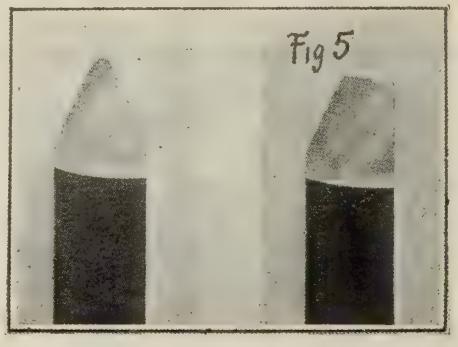


Fig. 5. Two similar tools, the one on the left being a very commonly used roughing tool, the one on the right being ground to conform to rule three.

This leads to the statement of a second rule, which is:—The least amount of cutting edge must come in contact with the skin of the work, if this is liable to damage the cutting-edge.

The third point to be considered is the absorption of the heat generated by the cut. This heat can be dissipated very largely by means of a copious bow of lubricant, but this will not prevent damage to the point of the tool unless there is a sufficiently large amount of metal in the tool nose to prevent the extreme point from becoming overheated. Any lubricant of coolant, which flows past the cut without touching either the tool or the work, is wasted from a cooling point of view. Therefore the broader the tool nose the greater will be the chance that plenty of cooling fluid will fall on it. It is a mistake to consider that any metal not directly concerned with the cutting-edge, should be ground away. All non-essential metal that can be left on the tool nose should be left, as it assists materially in absorbing and dissipating the generated heat.

The third rule, then, resolves itself into:—

The maximum amount of metal must be left on the tool nose behind the cutting edge to absorb the heat generated by the cut.

This rule is aptly illustrated in Figure 5, which shows two precisely similar tools as far as the cutting angles are concerned. The one on the left is a very common tool for rough turning and is to be found in many tool rooms at the present time. If, however, such a tool is ground as shown on the right, that is, with all possible metal left on the nose behind the cutting-edge, the life of the tool will be greatly increased, while the actual turning will not be affected in the least.

The three rules already discussed may be summarized as follows:—

(1) Maximum length of cutting-edge in action.

(2) Least amount of cutting-edge in contact with the skin.

(3) Maximum amount of metal behind the cutting-edge.

They do not apply to every case without exception, but should be adopted in the selection of tool profiles wherever possible. The exceptions will not be numerous, only presenting themselves when the cut is unusual or the work is frail and liable to spring under the cut

To illustrate the application of these rules, it will not be out of place to consider a specific case—say the turning of a forged shaft or spindle. How shall a tool be selected for the purpose? The decision will depend on several factors which may be stated thus:—

(1) Hardness of the material to be cut, and whether the work is annealed or not.

These affect the rake as much as the profile of the tool, and should therefore be taken into consideration when deciding on the rate of feed that it is possible to adopt.

(2) Whether the work has a hard skin or not. This has considerable influence on the choice of tool, as will be shown later.

(3) The strength, rigidity and power of the machine to be used. This will govern the depth of cut and rate of feed

(4) The solidity of the support the tool will have in the tool-rest. The single swiveling tool-post offers a poor support to the tool. The pattern with four clamping bolts and no overhang gives plenty of support to the tool and allows a much heavier cut to be taken than any other type.

(5) The frailty or otherwise of the work. If the work is liable to spring away from the tool, light cuts with a more or less pointed tool are necessary, otherwise the work will not be true and will be full of chatter-marks

As a first assumption the following combination of the above factors may be taken. The forging to be turned is 0.30 carbon steel, tough but annealed, therefore fairly easy to cut. The skin is clean and will not affect the tool very much. The machine to be used is one with plenty of power and strength, so that it will not be possible to overload it with the ⅜-inch depth of cut and ⅛-inch feed we intend to adopt, while the forging is also strong enough to take such a cut without spring. The machine will carry a tool of 1¼-inch by 1¾ inch section.

Rule 2 does not apply here as the forging has been annealed and skin hardness is unimportant. Rules 1 and 3 decree a long cutting-edge and a mass of metal behind the cutting edge.

Draw two parallel lines ⅜-inch apart to represent depth of cut, and two more parallel lines at right angles to these 1¼-inch apart to represent width of tool, as shown in Figure 6.

Next draw the line "AB," the intersection with the side of tool at "A" come about ⅛-inch outside the work, while the intersection with the top line at "B" should leave, say, ½-inch of metal to the right to comply with rule three. The tool shape is then completed by drawing a radius of, say, ¼-inch at "B" and a tangent to it at about 5 to 7 degrees so as to clear the work as the tool feeds along. We now have a tool profile as indicated by the lines shown in Figure 6. This tool profile gives a long cutting edge with an allowance for small variation in depth of cut, while plenty of metal remains at the back of the cutting edge to absorb the heat.

Such a tool is ideal for the class of work outlined. The angle which "AB" makes with side of the tool, side angle, Figure 1, is 55 degrees.

Now what changes, if any, are required necessary by variations in the factors previously mentioned. Suppose the forging is unannealed and has a s

.hat is hard enough to quickly wear away the cutting-edge. All three rules come into operation now, that is, in addition to the cutting edge being as long as possible, it must cut through the skin at, or nearly at, right angles to the surface of the work.

Turning to Figure 6 again, this means that "AB," instead of at 55 degrees to the side of the tool, must be very much steeper, even as steep as 5 degrees, while the long cutting edge is obtained by making radius of the point very little less than depth of cut. The resulting tool is similar to that on the left of Figure 7.

An alternative tool with exactly the same profile is shown on the right of Figure 7. This tool, however, has been sent to give an overhung cutting edge, allowing all the metal indicated by the shaded portion to be ground away by resharpening, before the tool is unfit for further use without re-making. This is a case where,owing to adverse conditions, we are forced to go against our better judgment by accepting a Round-nosed tool where we would use a straight angle tool similar to Figure 6, had there been no skin to contend with.

Our next supposition will be that the machine is not over strong and vibration set up under a ⅜-inch cut- ⅛-inch feed. Is it possible to maintain such a cut and feed by variation in the cutting tool used? The first point that arises is that the machine, unless there is something radically wrong with its design, must obviously be smaller than the one previously under consideration. It will therefore require a smaller tool section. Assuming this to be ⅞-inch by 1¼-inch, and following the method depicted in Figure 6 for determining its shape, it is obvious that the side angle cannot be 55 degrees; it will be about 35 degrees, as shown in Figure 8. It will be seen that with such a tool the cutting-edge is not so long, and end thrust on the tool will not be so great.

It is possible therefore that the tool depicted in Figure 8 will, on the weaker machine, take a ⅜-inch cut at ⅛-inch feed. If not, vibration can be overcome only by reducing the feed or the cutting speed, or both. It would not be wise to reduce depth of cut, if this can be avoided.

This exhausts the variations in the combination of factors previously named. It will be noted that all the tools developed to meet these variations are of the straight-edged variety. Exponents of the round nose will probably say this reasoning is faulty, that while admitting the straight-edged tool has some advantages, the round nose has more, especially where the work is excessively hard, as in turning shrapnel shell forgings. The reply to this is, that the obvious advantages of the straight-edged tool are combined with all those that the round nose can possess by grinding a radius on the point. The chip then tapers off to nothing at the point, while the thickest part is of even thickness and tends to curl away from the tool without absorbing more power than need be.

The importance of selecting the right profile of tool for any operation can be appreciated when it is realized that the right tool will

(1) cut at highest possible surface speed;

(2) need less re-grinding for work done;

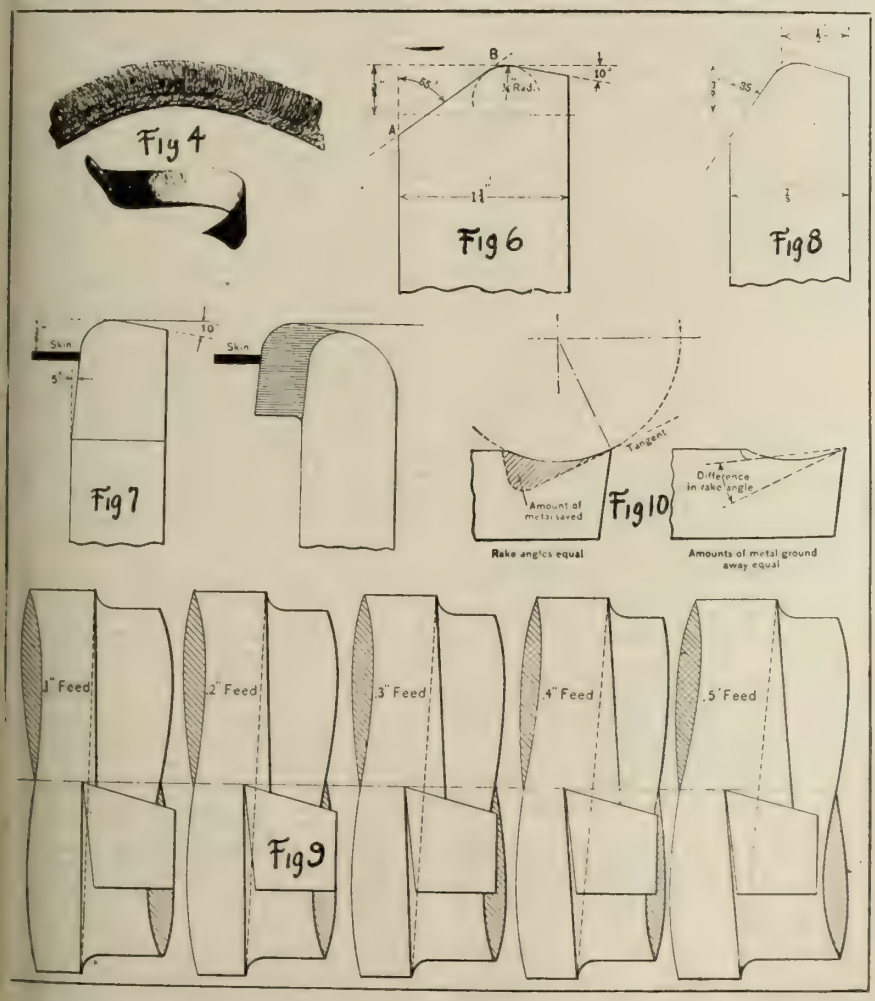
(3) always be more durable;

(4) help materially to increase output;

(5) when ground with the correct rake, use up the minimum amount of power.

Clearance.

The subject of clearance on cutting tools has, in the past, received scant attention from tool users. Everyone knows that clearance is necessary, though if asked why, most of them would be at a loss to give their reasons. If asked how much clearance a tool should have, they give the airy reply, "Oh, so much," as if the matters were of no moment and did not warrant any time being wasted on it.



Those, however, who have made a careful study of tools, realize that clearance is almost as important as profile or rake. Consider first these questions: "What is clearance for? Is it necessary? If so, how much clearance shall we adopt on different tools?

What is clearance for? To answer this, consider one or two concrete cases. Imagine a planing tool at work; if it has no front clearance underneath the tool, it will start cutting on the end of the work, but as soon as the cut has been started the tool will rub along the cut surface. Without having actually tried planing with a tool having no clearance, it is easy to imagine what will happen. Bits of chip get under the tool, terrific heat is generated and the tool becomes useless in a very short time.

This seems simple and logical, but when the action of a turning tool is considered there is a difference. The work being round, recedes from the cutting edge as soon as it passes it, therefore the tool action cannot be compared to that of a planing tool.

Then there is the question of side clearance, or clearance on that part of the tool which faces in the direction of the feed. In a planing or shaping tool precisely the same principles govern both side clearance and front clearance. In a turning tool, if the lathe is stopped in the middle of a cut and the ridge traced between the turned and unturned surfaces, it will be found to follow the path of a screw thread. In one complete turn round the work it strikes a point some distance behind the cutting edge of the tool as shown in Figure 9. It is obvious then that clearance on the tool is necessary, otherwise the side of the tool will not only rub along the ridge formed by the cut, but will actually prevent the tool from cutting at all.

Given then that clearance is not only desirable but necessary, what amount of clearance should be adopted as standard? On this point there are many different opinions. A little thought, however, will enable anyone to realize that the old proverb, "A miss is as good as a mile," holds good here. In other words,

Figs. 4 to 10. Fig. 4. Two pieces of chip, both made at same depth of cut and rate of feed. The upper chip was made by a round-nosed tool, the other by a straight-edged tool.
Fig. 6. Method of arriving at the profile of a tool when the conditions are all known.
Fig. 7. A suitable tool for rough turning when the work has a hard skin.
Fig. 8. A tool similar to that developed in figure 6, but having a smaller section.
Fig. 9. Relation between side clearance on a lathe tool and rate of feed. The tool shown has six degrees of clearance—ample for much more than the highest feed rate any tool would stand.
Fig. 10. The difference between a tool ground with curved top face and one with straight top face.

as long as the parts of the tool which should clear, do clear, that is all that is necessary.

As stated previously it is desirable that as much metal as possible should be left in the tool nose to assist in the transmission and dissipation of the heat generated. Further, the more metal that is ground away underneath the cutting edge, the less support the edge will receive to enable it to resist pressure of the cut.

This leads us to the logical conclusion that clearance must be as small as possible

Varying conditions would seem to indicate that under this rule, as stated, different clearances should be adopted for every different combination of factors. Can a standard angle of clearance be designated for each kind of tool and still conform, within reasonable limits, to the rule stated? Will any such tool, ground to standard clearance angle, adapt itself without alteration to all conditions to be met?

Perhaps the widest variation of circumstances will be differences of feed. In Figure 9 is seen the digrammatic representation of a 3-inch bar being turned at five different rates of feed. The tool angles are the same in each case. If then a tool can be found which will be equally suitable for the extravagant rate of a half-inch feed per revolution and the more ordinary rate of 0.100 inch per revolution, then the above question is satisfactorily answered. The tool shown in Figure 9 has six degrees of side clearance, which is the standard clearance for the majority of the tools included in the Lumsden chart. It is recommended, however, that five degrees be adopted as the actual standard in the finished tool, the six degrees being ground on in the roughing before hardening. In subsequent hand sharpening, it is then easy to just touch up near the cutting edge, when standard of five degrees or thereabouts is at once obtained.

There are many cases where even a smaller clearance than five degrees is desirable, especially in delicate tools such as parting tools. A parting tool is an example of clearance being reduced to a minimum. The sides of the tool nose taper from front to back one degree only each side and from top to straight top face or a curved top face.

Rake.

Watch a tool at work in any lathe, or planer; trace the path of the chip as it curls away from the cutting edge. A straight line drawn in the direction of that path from the cutting edge gives the rake of the top face of the tool. This applies whether the tool has a straight top or a curved top face.

Now there are as many different ideas on rake as there are men using cutting tools. One man likes a very keen rake; he takes the precaution of having two tools for each job, so that as soon as one is dulled he changes them and has the used one reground. Another prefers a smaller rake angle because his tool lasts so much longer. Still another prefers to use a tool with very little rake; chips come off in short curls all blue and violet, and it looks as if he were doing such a lot of work. The kind of tool for which a man shows preference is a fairly good criterion by which to judge his character.

Theoretically, the question of rake is extremely complicated. Practically, it resolves itself into a long series of compromises. It is intimately concerned with the nature of the metals being cut; thus, a different rake on a tool of any one profile is required for cutting hard and soft steels, cast irons, brass, bronze, copper, aluminum, etc. The theory of rake involves a problem that could not be exhausted in many articles of this description. while in the end the establishment of a set of standard tools would be no nearer than at the beginning.

The following statements on the subject are based on the experience of every tool user. Metals divide themselves naturally into a number of groups, summarized into those which are:

(1) Soft and tenacious, including very soft steel, and copper.

(2) Tough, but fairly easy to cut, including the majority of low carbon steels and certain kinds of bronze.

(3) Very tough and difficult to cut, including carbon steels, tool steel and most alloy steels.

(4) Brittle, including ordinary unchilled cast iron and some grades of bronze.

(5) Very brittle, including most brasses and chilled cast iron.

Each one of these groups requires a different rake, those in Class 1 a very keen rake, those in Class 5 little or no rake at all, while Classes 2 to 4 require varying degrees of rake in between the two extremes. The great majority of tools are required for Classes 2 and 4, therefore, if standards can be so framed that they cover the requirements of these two classes, while, with very little alteration, they can be made suitable for the other classes, the desirable quality of flexibility is introduced into the standard set of tools, the standards have been reduced to the smallest possible number of variations.

This matter will be gone into more fully upon consideration of what shall be included in the standard set of tools. The next subject for discussion is the relative merits of straight and cured top faces.

Curved Face Tools.

When the Lumsden oscillating tool grinder was first brought out in Europe, it was not fitted with any attachments by means of which tools with curved top faces could be produced. This type of tool was in such general use, all being united in insisting on its manifold advantages, that it became necessary to design an attachment which would enable such tools to be quickly and accurately produced. This attachment, however, now forms part of the standard equipment.

That the hollow-curved face has many advantages has been amply demonstrated already in many European plants. What are these advantages? They may be stated as follows:—

(1) They cut easily with the absorption of less power than straight-faced tools require.

(2) They permit the use of keen rake angles without weakening the tool nose.

Both these statements require proof, but the first cannot be proved on paper; it can only be demonstrated in the shop. It is a statement of fact, nevertheless, and anyone can easily verify it for himself by taking two tools of precisely similar profile and grinding one with a straight top face at the maximum rake angle he thinks the tool and the work will allow. The other he should experiment with, first by grinding a shallow curve in the top face and trying that; then he can grind the curve a little deeper and a little deeper still, trying it each time until he finds the cutting edge is so keen that it will not stand up to the cut. The experimenter will be surprised at the results he can thus obtain and will gain useful knowledge of properties of cutting tools.

The second reason can easily be demonstrated by a sketch. See Figure 10. The rake at the extreme cutting edge on a curved face tool is equal to the angle made by a tangent to the curve at that point; a tool, therefore, to have the same rake as the curved face tool shown on the left in Figure 10 must be ground to the absurd shape indicated by the non-shaded portion.

On the other hand two tools from which an approximately equal amount of metal has been removed are shown on the right hand in Figure 10. Here the extra keenness of rake obtained by grinding the top face wtih a hollow curve instead of straight is clearly shown.

This leads naturally to whether such a keen rake is desirable. The experiments mentioned above will prove that wherever rake is desirable at all, a curved-face tool will give better results and more efficient cutting than a straight-faced tool. The curved face seems to lend itself to the curl of the chip, which comes away more freely and with less effort than from a straigh face.

That the curved face is more natura is also shown by examination of an straight-faced tool that has been use for taking heavy cuts in steel. If th tool has been used for a reasonabl length of time and is still cutting well it will be noticed that at the extrem edge a small portion of the steel bein cut has fused itself on the tool, whil immediately behind the chip has carve a curved face by wearing the metal c the tool away.

In conclusion, years of experience de voted entirely to the manufacture an application of tools for use on hundred of different machines under a very larg variety of conditions, have demonstra ed that wherever a curved face can b given to a tool, it makes a better too for all-round general use than is eve possible with a straight-faced tool. Th amount of rake to adopt for all tools varied and dependent upon each sepa ate tool shape. In a later article, th question will be further discussed.

AN ALL OIL NAVY.

Naval experts and shipbuilders in a parts of the world have been much in pressed by the decision of the Briti Admiralty to build only oil-burnin ships in future. Many reasons ha combined to bring about this decisio Among them are the convenience transporting oil and storing it at strat gic points, the small space which occupies on board ship, the ease wi which oil may be taken on board sh from tanks or tank steamers, the sim plification of stoking, and the high ef ciency of the fuel. It is calculated th even at present prices oil is cheap than coal as a fuel, apart from t other economies enumerated. This of cial decision is likely to give a fill to the movement, already taking pla rapidly, for the conversion of lar liners and other merchant vessels flyi the British flag from coal-firing to oi firing. One benefit of the change w be to do away with the terrible con tions to which stokers, on coal-fir ships are subjected, especially on t pical seas.

A Talk on Gauges And The Art of Guage Making

Mechanics Are In a General Way Familiar With Gauges But The Details Incorporated In Such Tools Are Not Understood—Various Types of Gauges—Their Purpose And Constructional Details.

By F. SCRIBER

THE subject of gauge making is one in which interest of late years has become quite general. Regardless of the class of work handled or manufactured some limits must be established to control one's product within a reasonable degree of uniformity. In addition, where a high class of interchangeable work is wanted, high-class gauges must be employed.

In a general way mechanics are familiar with gauges but it has been the writer's experience that the same mechanics are not familiar with many of the finer details which are incorporated in these tools by manufacturers who specialize to some extent in their manufacture. It would of course be attempting too much to attempt to enumerate all the details which occur in diversified gauge manufacture, and it is therefore my object to present in this discussion simply a line of thought with a few illustrations emphasizing the points at issue. One of the most common types of gauges is the plug gauge which enters a hole to measure its diameter. These are often made with "Go" and "Not Go" diameters, varying a few (or even less than one) thousandth part of an inch.

Figure 1 illustrates three types of the plug gauges, the one in the center being of the type most commonly used. In this construction the center portion is knurled for convenience in handling as this makes a rough gripping surface. The knurled portion has a flat milled in it which provides a space for marking the tool with part numbers or other information, including the word "Go" at one end and "Not Go" at the other. The smaller diameter A, which is the "Go" end is made longer than the B diameter, which is the "Not Go" end. The object of this is to allow of grinding the end of the A diameter, as the corner of this becomes rounded or worn through use. It is seldom necessary to grind the end of the B diameter as it does not enter the hole of the work except when the work is oversize. This gauge is necked to provide clearances for the grinding wheel which grinds both end diameters accurately to size.

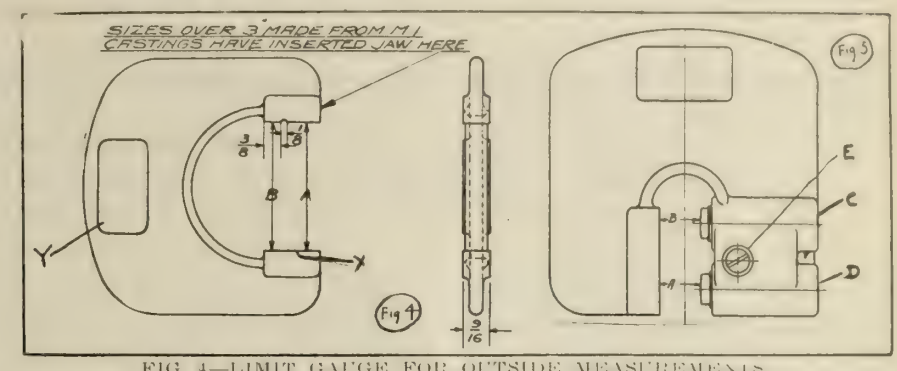


FIG. 4—LIMIT GAUGE FOR OUTSIDE MEASUREMENTS.
FIG. 5—EXTERNAL GAUGE WITH ADJUSTABLE PLUGS.

Other Types.

The upper illustration shows a gauge used for the same purpose except that its ends are drilled and reamed, while plugs are soldered in place for the "Go" and "Not Go" diameters, this eliminates to a large extent the difficulty encountered when hardening a small diameter integral with a large diameter due to breakage, while it facilitates replacement as the plugs can be removed from the handle by heating, when new plugs can be substituted.

In the lower view is shown a gauge which has both the "Go" and "Not Go" diameters at the same end. This gauge is built on the principle that the A diameter will go into a hole, while the B end will not go into it. It of course is used without reversing. This complete gauge drawing is made up with letters in the dimension lines and a chart to be filled in is provided in the lower portion of the sheet. The first column in this chart is for filling in the number of gauges required while under "Go" and "Not Go" are spaces which are filled in with dimensions as required. Under the word "Blank" is filled in the style of gauge required, this being one of the three shown, while the style required number also indicates a stock diameter of blank carried in the stores department for grinding to the size wanted. Under the word "Mark" is placed the designation which must appear on the flatted surface of the gauge.

Figure 2 illustrates two other types of plug gauges, the essential difference between these being that in general they are used for larger sizes of holes. They consist of handle X, upon which are placed bushings Y, held thereto by a screw Z. Type 1 has a bushing having one diameter only. This is used where it is desired and have the plug a ringing fit in the hole, or for any other purpose where a single diameter gauge is sufficient. Type 2 represents a "Go" and "Not Go" gauge having a minimum gauging diameter B, and a maximum gauging diameter C. This has the same general characteristics as one of those shown in Fig. 1.

Still another type of plug gauge is shown in Fig. 3. This consists of a holder A having a long bushing B, which is made with a small or "Go" diameter, and a short bushing C, which is made with a "Not Go" diameter. This type of gauge is very economical on large holes as one handle can be used to accommodate a number of gauging bushings, thus enabling one to build up a suitable gauge at a minimum of expense.

Two types of external gauges are shown in Figs. 4 and 5; the first of these, Fig. 4, is made from a steel forging, or in the case of the larger sizes from a malleable iron casting. These

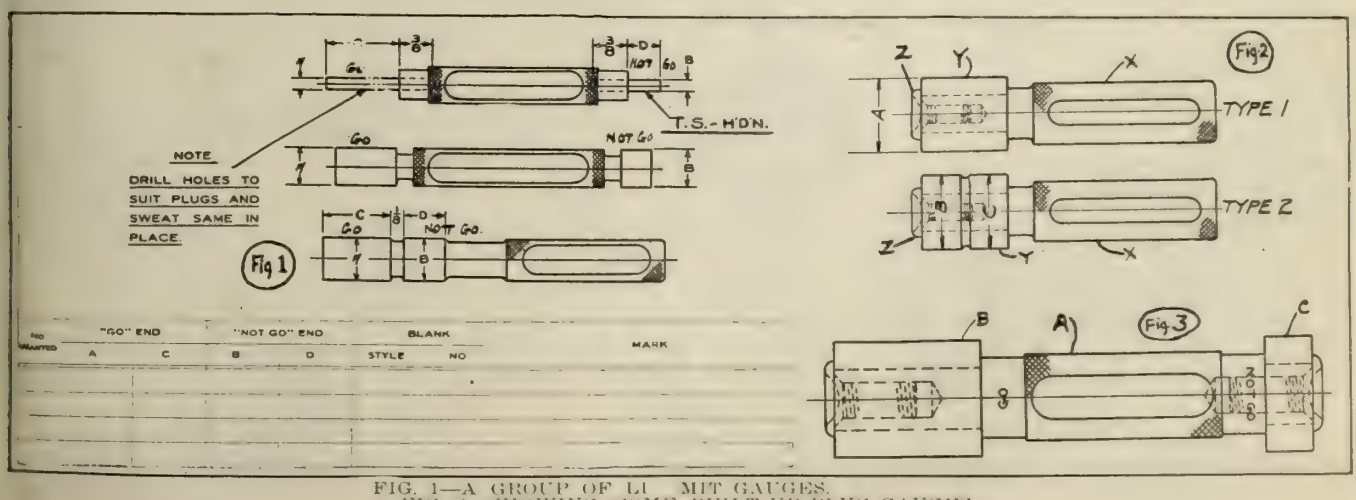

FIG. 1—A GROUP OF LIMIT GAUGES.
FIG. 2—SHOWING SOME BUILT UP PLUG GAUGES.
FIG. 3—DOUBLE END BUILT UP PLUG GAUGE.

gauges have two diameters A and B, these being the "Go" size, A, which will go over a piece of work, and the B size which will "Not Go" over a piece of work. The lower gauging surface X (as will be noticed) is made flat and all of the difference is obtained by grinding a step in the upper gauging surface. It will be noticed in this connection that the length of the "Go" step A is much greater than the length of the "Not Go" step B to allow for wear of the "Go" step. A finished surface Y is provided for marking the gauge.

In Fig. 5 is shown a gauge for the same purpose having buttons inserted in its right hand portion. The work being measured would "Go" through A but would "Not Go" through B. Such gauges are adjusted with a screw behind the plugs at C and D, while a screw E is used for locking the plugs when they have been adjusted to the required dimension. Gauges for this same purpose are often made of flat stock while in the case of the gauge shown in Fig. 4 steel inserts are put in the gauges where indicated if malleable iron castings are used.

Some Essentials of Modern Pyrometer Equipment

Subject is Divided Into Three Distinct Parts—Important Factor is Simplicity of Design—Internal Cold Junction Compensation Details—Cost of Thermocouple Upkeep—and Other Interesting Points.

*By H. G. HALL

IN a pyrometer steel treaters have been asking for an instrument that is accurate, but the tendency seems to be to sacrifice considerable in the other features to obtain accuracy. While it is admitted that accuracy is of prime importance, other features are to be considered. The subject naturally divides itself into three distinct parts: (1) The instruments; (2) the leads and (3) the thermocouples. It has been found that the instrument to give the most satisfactory results should have a resistance of about 250 ohms across binding posts. This is for plant use of course and seems high enough to eliminate the troubles due to changes of external resistance. Careful tests have shown that just as accurate results can be secured with this amount of resistance as is found in the higher resistance meters, thus it is not necessary to sacrifice further ruggedness for the additional ohms resistance.

The indicating instrument should have a very clear and readable scale, instruments supplied with a spotter being advantageous for shop work, particularly when the temperature is to be maintained constant. An instrument void of chamber error certainly is one of the very important features to be remembered in making the selection because of the fact that some meters have a chamber error amounting as much as 40 degrees which makes them useless to the steel treater.

The discussion might be carried further as to whether the instrument should be of the suspension type or of a double or single pivot movement. The fact is, that it is necessary to have an instrument that will stand the ordinary amount of vibration found in a shop. The highest grade of double pivot movement has answered the requirements very well as it seems to be least affected by vibration. Careful tests show that this type of instrument gives the desired degree of accuracy.

The chamber error has been found to be one of the important causes for trouble. This is a very annoying situation because many do not know what is causing the inaccuracy and it is difficult to correct without replacing the meter.

While the recording type instrument is used in some cases as an indicator as well as a recorder, the most important factor is simplicity of design. It must at the same time make clear and readable records. Obviously, a steel treater does not want a recorder that will require constant supplying of repair parts and in this way, take his attention from other work, which involves considerable annoyance and added expense.

It has been found that recorders giving the continuous automatic records are to be preferred to those that give numbers from which the curve can be drawn later. The charts made should be easy of access and easy to file, thus the principal feature in connection with the use of the recording pyrometer should be simplicity of construction. Surely the simplest mechanism, other parts being equal, will require the least care and the least amount of rechecking.

In considering leads or couple extensions one must consider the proper kind of insulation for the wire to meet the plant conditions. In many cases it is necessary to use asbestos-covered wire where rubber-covered wire would not be satisfactory, and vice versa. The couple extension is one of the important features of every pyrometer equipment. A number of steel treaters using pyrometers have installed in their plants what are called "compensated leads" although the term is not commonly understood.

Certainly this term should be defined clearly, thus possibly the term flexible couple extension carries the idea more clearly than compensating leads. The latter seems a misnomer because these leads do not actually compensate. This brings us to the consideration of the error due to the cold junction variation in temperature. On some pyrometer equipments the cold junction is buried in the ground and on others it is put in the hot water or steam jackets; and on still others it is put in regulating boxes controlled by lamps. Recently some steel treaters have put the cold end in a box of a special powder in which the cold end does not vary more than plus and minus 5 to 10 degrees Fahr. While it is true that these methods of installation have been satisfactory under certain conditions, they have not met the universal requirements for eliminating the error due to the cold end. It is very expensive under many conditions to bury a cold end for blasting in rocks or concrete often is required. Water jackets will leak in time and cold end regulating boxes are just an additional part of the equipment to require care. It must be borne in mind

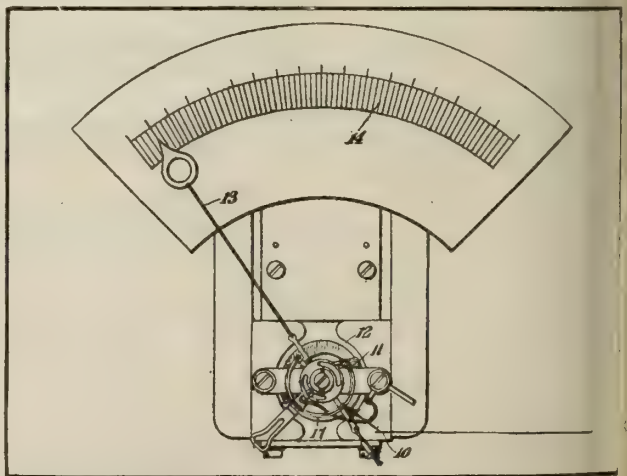

FIG. 2—DETAILS OF CMPENSATOR CONSTRUCTION.

onstantly in using the pyrometer that he electromotive force developed de-ends upon the difference in tempera-ure between the cold junction, which s outside the furnace, and the hot junc-ion, which is in the furnace.

Cold Junction Compensator.

An internal cold junction compen-ator has been developed and tried hich operates automatically and does way with the necessity for burying the old end in the earth and eliminates the se of any other outside means for regu-ting the temperature at the cold end. t is enclosed in the instrument itself, ne end of the internal spiral compen-ator—for such it is called—being at-ached to the pointer while the other nd is securely fastened to the instru-ent. The method of using the compen-ator is illustrated in Fig. 1. It is satis-ctory for use on either base metal or recious metal couples.

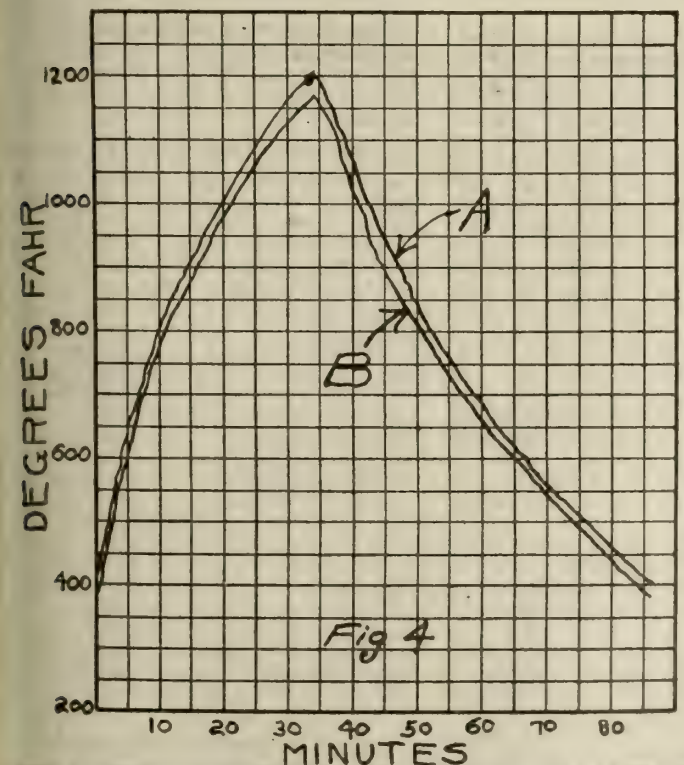
Of course, in using this compensator is necessary to run the same kind of aterial that is in the base metal couple the instrument itself. In the case of n installation of an instrument with a ompensator for a manufacturer of ank shafts for automobiles, the tem-erature of the oven was maintained at 0 degrees Fahr, and readings were aken across the entire scale, the read-gs being within ¼ to 1 per cent. Many her companies are using this compen-tor with similar accuracy.

It is also very gratifying to find that is *compensator has worked out so tisfactorily because it is the result many years of experimentation on a itable device for accomplishing this sult. Elimination of the chamber er-r in the instrument and the error due the cold end temperature, overcomes o of the chief objections to the use the thermoelectric pyrometer, and akes it possible to use this instrument r very low ranges of temperature with high degree of accuracy. Accuracy well within 1 per cent. for ranges of temperature is secured over the entire scale where the maximum reading of the scale is only 600 degrees Fahr.

In cases where a previous metal couple is used, the platinum wires are not run to the instrument but substitute patent alloy wire is used that carries the cold junction to the instrument and serves the same purpose for shop use as if the platinum were used for the entire length. The steel treater interested in accurate results from his pyrometer can obtain a great deal of satisfaction in knowing that his cold end errors are entirely eliminated. In other words the equipment is operated as though it had no cold end.

In Fig. 2 the details of construction of the compensator are more clearly shown. The indicating arm 13 is operated by the usual moving coil 11. A small portion of the control spring 12 is shown, but instead of the end of this spring being secured to the abutment, it is attached directly to the end of the spirally curved piece of thermostatic metal 17 and the other end of this thermostatic coil is carried by an adjustable abutment allowing for initial adjustment of the indicating pointer, to make its position on scale agree with that of room temperature.

The temperature variations of the room cause the thermostatic spiral to wind up or unwind, maintaining the correct position of the indicatng arm, regardless of room temperature. When the thermoelectric couple with extension-piece, as illustrated in Fig. 1, is carried into the compensated instrument, no corrections are necessary for the thermocouple cold end temperatures at any point on the scale. The compensator also may be made to serve a double purpose, since by a slight variation of its length it may be made to correct automatically for the temperature coefficient of the wire forming the moving coil of the millivoltmeter.



Comparison of Readings.

Fig. 4 shows curves A and B and is a comparison of readings of a laboratory potentiometer and a compensated pyrometer. The platinum couple was used with the potentiometer with the cold junction maintained at 32 degrees Fahr. in the bath. The temperature of cold junction of the pyrometer was maintained constant at 70 degrees Fahr. In Fig. 5 the temperature of the cold junction of the pyrometer was maintained at 130 degrees Fahr. in the oven while the cold junction of the potentiometer was maintained at 32 degrees Fahr. as in the case of Fig. 4. These readings were taken by an automobile manufacturer and illustrate the accuracy of the compensated pyrometer, the difference between the two instruments being practically constant throughout.

It is very important in the use of proper thermocouples that the couples produce the same electromotive force although the wires may be almost burnt off. Of course, in case the thermocouple does not give the same electromotive force, an error will occur in the readings, but with the advances made in manufacture of thermocouple alloys, this source of error has been overcome.

Although shunted thermocouples have been used with some success, the practice of using this idea as universal is not advisable because of the errors which are certain to result. The chief difficulty is that under most conditions the fire end is not always inserted the same distance into the furnace or tempering bath. With the advances made in developing alloy metals it has been found more practical to use base metal couples of selected material. These can be secured easily with a guarantee that readings will be within plus and minus 3 degrees Fahr.

The cost of thermocouple upkeep is, of course, important but this can be reduced very appreciably by making a thorough and careful study of the con-

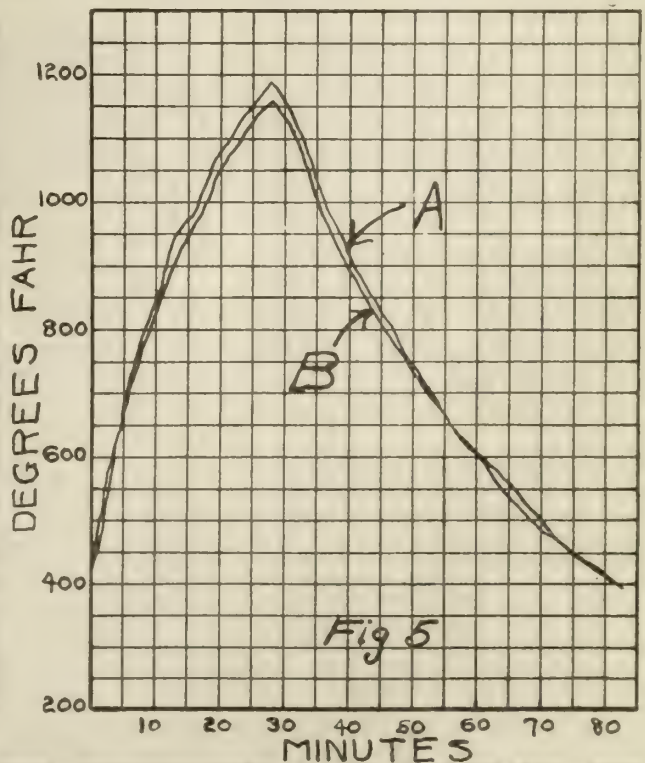


FIG. 4—COMPARISON CURVES OF READINGS OF LABORATORY POTENTIOMETER A, AND COMPENSATED PYRO-METER B. IN THE FIRST CURVE COLD JUNCTION MAINTAINED AT 32 DEGREES FAHR., AND IN SECOND, CURVE MAINTAINED AT 70 DEGREES FAHR. FIG. 5 SAME AS FIG. 4, EXCEPT COLD JUNCTION OF PYRO-METER IS MAINTAINED AT 130 DEGREES FAHR. BOTH FIGS. 4 AND 5 SHOW AN ALMOST CONSTANT DIFFERENCE BETWEEN THE CURVES.

ditions. This includes study of the gases that are emitted from the fuel, as the oxidization of the steel or other articles in the furnace takes place. One prominent automobile manufacturer whose couple expense on about 500 couples constantly in use was about $1.00 per month, by very careful investigation of the conditions and proper protection of the thermocouple reduced this cost to $0.27 a month. In this case, the manufacturer was using precious metal couples.

A manufacturer of roller bearings, who is using the potentiometer system, states that his couple upkeep was $12 per year, which is not excessive for platinum couples. This cost includes only maintenance expense for the couples and not the maintenance on complete pyrometer equipment whereas the case just mentioned of 27c per month includes maintenance on the entire ou fit. In the former instance the upke of the entire equipment is include Here the galvanometer system was use From all the data the author was ab to obtain, it is evident that the upke on the potentiometer systems were f in excess of the maintenance cost on t galvanometer system especially whe potentiometer recorders were in use.

A Recital of Casting Troubles. What is The Remedy

What Is The Remedy For Such Expensive Troubles? Do Others Have Similar Troubles With Machine Shops, or Is The Foundry Turning Out a Low Grade of Work?

By DONALD HAMPSON

OUR shop accomplished manufacturing work of a wide range. The lightest piece we sold weighed three ounces, the heaviest 1,200 lbs. There were a total of nearly a million a year of the former of various shapes and sizes, about three hundred of the latter. All were made in grey iron and most of them had to be machined all over. The small work had been gated and metal patterned in the most approved style. Our large pieces were cast from wood patterns with metal ribs judiciously distributed, and there were about twenty of the patterns, all of the same shape and thickness but of different areas. These were the simplest kind of pieces to mold. All we required was true, clean castings; a difference in size did not bother us if it did not exceed a quarter of an inch. There was not a core in a single one of our castings.

This recital briefly covers our foundry needs. We buy all our castings because we want to devote our attention solely to making and marketing a satisfactory product. I would say that I never have known a line of either small or medium sized work that was so simply and easily molded—and it ran into so much weight at the same time! It was the kind of work a foundryman would dream of. We paid about the market price for similar work but we protested this price nevertheless on the grounds of the losses we sustained from the castings and from the fact that it was steady work the year around.

Most ships' requirements are bunched in one busy season and fall off during the rest of the year, they have patterns with deep "draws" and many cores to set, and their work includes those few-piece jobs and awkward specials on which a foundry loses but says nothing because they have to take them to keep the other work.

Anyone would have thought that foundries would have fought with each other to get such a line of work. They do not. We would have preferred to put our larger work all at a local foundry and our smaller, strictly manufacturing, parts at a foundry equipped for just such a line. But we learned from bitter experience not to depend solely on one source of supply. Then, too, we never struck any foundry that would produce the quantity we needed. And all the while the price of castings would keep going up—first it was on account of sand being high, and then labor and then pig and then coke; we paid all these increases grudgingly because every twenty per cent. raise meant a loss for us, who had competition to meet and could not possibly raise more than five.

We would get our prices all fixed up and would put in an order for ten thousand casts from the G-12 gate, delivery to begin in a week. At the end of a month we would be out of these pieces and would have had no response to our letters. Why is it that foundries are so lax about their correspondence? If I can't do a piece of work or keep a delivery, I say so like a man and do not build up false confidence in a customer's mind. He is at least given a chance to get the work elsewhere. But not your foundry. The first wire after the third letter may bring a small bag of G-12's by express. That's your first response.

Then there's the zig zag casting. We've gotten thousands of castings in a shipment (and had to make them go by a long costly process of filing and grinding because we had no other) that looked as if the moulder had been blind or had closed his eyes and pasted two halves of the casting together in the dark.

What Became of Our Hopes in the Automobile Field.

It was just after the war and we felt free to at last develop an automobile specialty that we had been holding up. We had reached the point where our patterns were completed but to our surprise found that none of our foundries would take any more patterns. That stumped us but we shopped around through a wide radius, finally learning that the malleable iron Co. had the only grey iron foundry in the country that wasn't busy. We soon learned why.

A representative came to see us. We explained our specialty to him and showed him our patterns. Yes, they could make us the finest kind of castings—castings that would sell our product on sight—they would probably cost about 20 cents a pound, but he would quote exact figures on his return to headquarters.

We displayed a few castings made locally, along with the patterns. Mr. Representative proceeded to pick flaws in each. "Now we wouldn't send out any castings like this—that sand flaw there, that sunken spot, that place where the checkerboard isn't perfectly filled out, that sprue that wasn't ground off—why, our inspectors would throw all those out on sight." (Thank heaven, we had found a foundry at last that understood its business). "And your patterns, they need a lot of fixing up. That pin hole, and that, and that, will have to be filled up and that line where the solder shows would leave its mark c the castings and I don't think they a gated level. We can't turn out castin from such poor patterns—our men can do a good day's work unless they ha somethings to work with." (We thoug our patterns were the best metal pa terns we had ever seen).

Can. Mach. July 14 Galley 5—

A few days later we got the "quot tion." They wanted 22 cents a pou for the castings and they would ha to make a pattern charge of $120 to r make our patterns. We accepted th extortion because all other foundri were full; and we breathlessly await the castings. Anyway, we would sa money through not having to grind a chip and file. They came—four barre with 500 pieces in each. Imagine o chagrin to find them hardly up to t quality of the local jobbing foundry' sprues and gates left on, sand holes a air holes, checker creases entirely fill up, etc., etc. For once we forgot o first grade credit rating and gave ve to our feelings. We had Tony whe the four barrels to our scrap heap a dump them, then we wrote the partic lar Co. in choice terms, telling the where they could get their castings they wished and to go ahead and t to collect.

Why Store Away Broken Patterns?

Another annoying practice is the r turn of broken patterns. You write phone to the foundry to hurry a tho sand three-inch plugs. A week later package arrives with what you thi might be the first three hundred, ju to get you started. Imagine your su prise when the package proves to co tain the plate with parts of several pa terns broken off. You had every reas to think you could complete the ord of a thousand in two weeks and y wrote your customer to that effect aft wiring the foundry to hurry the j through. Instead, the foundry nev replies at all and your first intimati that they "register interest" is the a rival of the broken patterns; instead wiring immediately or repairing the themselves, the foundry disregar hurry requests, and in its own swe time, dumps the stuff flat on your hanc An incident of that kind makes the ha assed executive long to read that typ mistake over an obituary of some fou dryman, "Gone to His Long Roast."

Another Big Foundry Qualifies.

One more example and I rest the ca The steel foundries solicited our larg work of a part that we used two hu

WHAT OUR READERS THINK AND DO

MAKING A PUMP ROD.

By J. H. M.

Considerable interest has been taken in the articles written around the manufacture of a pump rod, the original drawing of which appeared in the April 15th issue of Canadian Machinery. On May 26th we published a complete story of how the Jones & Lamson Co., Springfield, Vt., would suggest making such a rod, and in this article we gave a production time of 11 pieces per hour.

Since that time, another reader of Canadian Machinery, who is specially interested in machine tools, wrote Ralph E. Flanders, manager of the Jones & Lamson Co., suggesting that the time given was theoretical rather than practical. The result was that Mr. Flanders, to satisfy both the readers of Canadian Machinery, and himself ordered the piece to be set up on the machine once more to make sure the production figures were correct.

The Result.

The result of the test has been forwarded to our office for inspection, and the rod as forwarded is assuredly a good commercial job. The finish is good and the dimensions accurate. Mr. Flanders gives us some interesting figures regarding the test. He states as follows:—

The pump rod was made in four minutes and 32 seconds, or a production rate of slightly over 13 per hour. The piece sent is one of several made at that rate by three different operators. The turning operation, which is the most spectacular part was accomplished at the rate of 150 ft. per minute surface speed, or 280 r.p.m. The feed was .030 in. per rev. and the tool used was stellite No. 4, as high speed steel would not stand up to this speed.

Mr. Flanders then goes on to state that while the figures he gives are actual production ones, he is inclined to believe that for general estimating a somewhat slower time should be considered. An operator who is attending to business, according to Mr. Flanders, should turn these rods out at from 6½ to 7 minutes each.

SOLVING RIGHT ANGLED TRIANGLES.

By JOHN S. WATTS.

Both in the tool room and in the drawing office, it is often required to determine the length of one side of a right angled triangle, given the lengths of the two other sides, and in practically all cases, these dimensions are given in fractions.

The calculation includes the squaring of the length of the two given sides, and taking out the square root of their sum, as is well known, but the tables of squares and square roots are given only for whole number, and to use them gives us only an approximate answer.

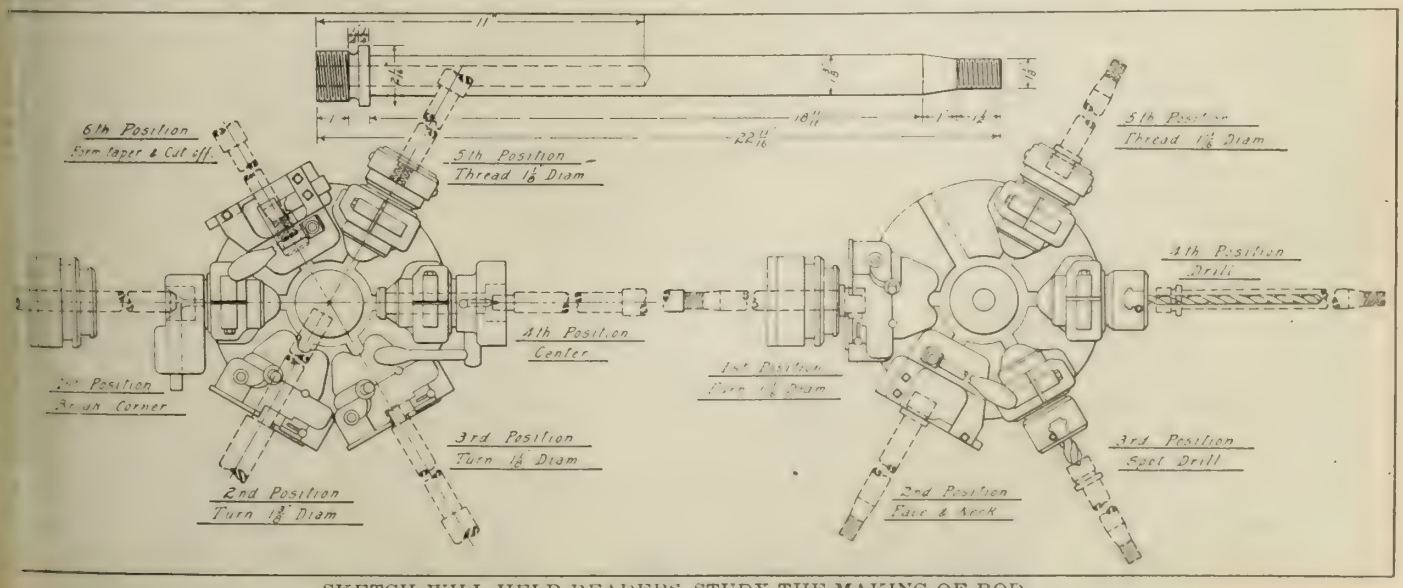
Take for example the solution of the triangle shown in the accompanying figure, we first convert these into decimals, as 11.375 and 6.625, and looking up our table of squares of numbers, we find that it only gives numbers up to four digits, and we have to take the nearest, by taking the squares of 1137 and 663. These are respectively 1,292,769 and 439,569, the decimal point being two places to the left in 11.37 and 6.63, will be four places to the left in the squares, (that is twice as many) and the square are 129.2769 and 43.9569, the sum of which is 173.2338.

To get the square root of this number, we have to look in the column of squares, and find that the nearest square is 1731856, which is the square of 1316. Noting that the decimal point is four places to the left in the square, we place it two points to the left in the number, and find that the square root is 13.16, which will be approximately the length of the unknown side in the triangle.

A much shorter and more accurate method is to convert the mixed numbers into improper fractions, having the same denominator, the numerators then being full numbers, their squares can be exactly determined from the table of squares, and adding together these squares, we have a full number, whose square root can be determined approximately from the table, (exactly in cases where this number is less than the highest number in the table) and this square root is the answer required.

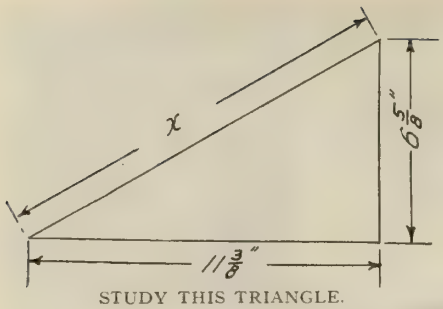
Working out the example taken above by this method we have:

$$= \frac{11\frac{3}{8} \times 6\frac{5}{8}}{8} = \frac{91-53}{8}$$



$$= \frac{8281-2809}{8}$$

$$= \frac{11090}{8}$$



$$= \frac{105.3}{8}$$

= 13.1625 or 13 5/32 to the nearest sixty-fourth.

If accuracy to a thousandth of an inch is needed we must work out the square

SKETCH WILL HELP READERS STUDY THE MAKING OF ROD.

STUDY THIS TRIANGLE.

root of 110.90, which is equal to 13.1636, which shows that the error when worked out to the last method is only one thousandth of an inch. whereas by the first method we would be out three thousandths, due to having to approximate three times in the first method against only once in the last.

The greater accuracy of the second method is due to the fact that we get whole numbers to work with, the squares of which can be got exactly from a table, and the sum of these squares is also an exact whole number, and being a larger number than by the first method, the square root can be approximated from the tables more accurately, and if need be can be calculated with any desired degree of accuracy.

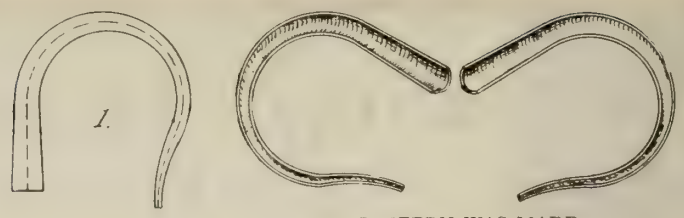
If the same degree of accuracy is to be had, the calculations by the first method will be much more laborious, as the square of the two sides would have to be calculated, because no table is comprehensive enough to take in figures having so many digits. Furthermore the first method takes a longer time, even when only approximate results are desired.

CROSS INDEXING MECHANICAL INFORMATION.

(By F. M.)

A very convenient method of indexing miscellaneous information, such as is usually accumulated from catalogues, notes and magazines, is shown by the accompanying chart. This chart may be used where the information indexed is placed in regular letter files, cabinets or most anywhere that a letter of numbered system is used.

Referring to the chart it will be noticed from the title that this index refers to "File number 1," from January 1918, to a date which is to be filled in when a new index sheet and additional file is developed. Below the title in the diagonal spaces are major titles such as Lathe, Milling, Planing, etc. In the column at the extreme left are a number of sub-titles. Intersecting lines running from both of these titles form spaces in which letter or numbers are placed and reading down from one column along the top and across from a column on the side; by noting the letter in the space which they form where they intersect, it is apparent that the subject matter so designated is filed under that letter or numeral.



For example, we will presume that it is desired to look up information that has been accumulated under "Advertising Forms." Looking along the top we find the word "Forms," and glancing down the left hand column we find "Advertise," while in the square where the two intersect, is the letter "V." One would therefore look into the file "V" for the information desired; likewise if it was desired to find information in regard to drilling machines, one would look along the top to the word drilling; along the left to the word machines, and at the intersection of the two is the letter K indicating the file to be looked up,

A chart of this nature can be easily compiled to suit individual requirements and may be more or less extensive. It can be pasted on a card and makes a very handy visible index,

A DETAILED VIEW OF THE CROSS INDEX.

SHOWING HOW THE PATTERN WAS MADE.

IMPROVISED CASTING PATTERN.

By CHAS. E. HALL.

A jewelry manufacturing concern, having secured an order for a bishop's crozier in sterling silver 6 ft. 6in. high, which was to be made according to a specified design, and such articles not being in every-day demand, it was essential that the cost be kept as low as possible, particularly on account of the difficulty of estimating on a first order of this nature.

The crook section was about 18" over all, and a gradual taper from 1" in diameter at the large end, to ⅜" in diameter at the other. A local patternmaker quoted $35.00 for a core box and pattern, a price which the estimate made prohibitive. It was decided to make the pattern in the shop, and the method adopted may help out in other fields.

A tracing was made of the outline of the crook from the drawing, with a center line drawn the entire length, as in Fig I., and primed down on the drawing board. A piece of wire was bent to conform to the center line to obtain the exact length, and a straight tapered wooden pattern turned up, the length of the wire, ⅞" thick at the large, and ¼" at the small end. In other words, less two thicknesses of metal or ⅛". A piece of 2" pipe of suitable length, was used as a moulding box, and the wooden pattern rammed up in sand, and a lead cast taken. This was filed smooth and bent to conform to the shape of the crook, and lightly coated with beeswax. Strips of paper were wrapped round the lead core; shellaced, and allowed to set. There happened to be on hand a few bolts of damaged silk ribbon about ½" wide which came in very handy.

This was then wound on, shellacing each layer, till it was built up to the diameter of the crook. Two or three layers of paper were now added, to allow for filing and polishing, and when perfectly hard, was cut into two halves with a sharp knife—as shown at Fig. 2, and lifted off the lead core, the bees-wax preventing it from sticking. Using these as patterns, the two halves were cast in silver, filed flat on the edges, hard soldered together, and the crook filed up.

By this method the whole job of making the pattern only occupied about three hours, which was a decided saving on a pattern and core box at $35.00.

LARGE CASTING.

One of the largest, if not quite the largest steel ingot mould ever made was recently cast in Great Britain. It is over 15 feet long and its diameter is over 9 feet. This mould, which will be used for the casting of steel, was so huge that it was almost too large to be conveyed on the railway, and great ingenuity was exercised in arranging it for transport. It was carried on a huge steel girder which rested on two 8-wheeled trucks, between which the mould hung. The weight of this record casting was 87½ tons.

Development In Machine Tools Has Been Stimulated

Automobile Industry Has Influenced the Design and Construction of Machine Tools—Motor Demand Has Made Possible Continuous Production—Lubrication the Big Problem.

By F. K. HENDRICKSON.

DURING the years 1910 to 1913 the automobile industry began to exert a great deal of pressure on machine tool manufacture and design, and about this time several concerns found it necessary to make extensive and expensive changes in their systems of production to meet the rapidly increasing demand for cars. To arrive at the best conclusions and in order to secure the most modern installations, they invited many of the best engineers and machine tool manufacturers in the country into conference with them. Each individual piece was considered separately and at times in the presence of two or more representatives from different firms, with the result that highly specialized machines were rapidly developed.

Every mechanic is fully aware of the extremely rigid construction which has been demanded, due to the strains to which machines are subjected. In addition to the extra weight thus entailed, materials of high tensile and torsional capacity have been substituted. Lathe spindles originally of 0.30 to 0.40 per cent. carbon steel are now made of 0.15 to 0.20 steel, being carbonized and hardened to produce glass hard surfaces. The diameters also have been greatly increased. Lathe centers formerly quite small, unhardened and of low-grade tool steel are considerably increased in size and hardened at the point on both head and tail stocks; in fact, centers are now produced commercially having high-speed hardened points, either inserted or welded to the shank.

High Speed Tools.

High-speed cutting tools generally supported in special rigid holders are replacing almost entirely carbon steel lathe and planer tools, twist drills, reamers, milling cutters, taps and dies. Babbitted journals or bearings are rapidly being replaced by the best quality bronze metals, and the tendency is toward the application of ball bearings. Certain types of machines have already been forced to incorporate them on their main spindles and with success, which indicates that the same conditions will ultimately obtain in other machines.

In addition to producing gears of wear-resisting qualities, it has also been necessary to develop their efficiency and to produce much quieter running. To accomplish these conditions, several machines are to-day equipped with helical or herringbone gears to produce smooth action and silent running under high speed and strain. New forms of spur gears are also being developed which are claimed to successfully meet the requirements.

Precision and Specialization.

Grinding machines have been brought to a high state of perfection and produce a truer and finer quality of work in all revolving and sliding parts much more rapidly than ever before. Closer limits and tolerances have been demanded, with the result that the all-round mechanic has been replaced by the present specialized expert, in order to obtain the highest grade of precision in quantity.

Along with the added strength and rigidity of the machines must necessarily be considered their power. Extra large driving pulleys; cones; single, double and triple back gears; and worm and worm gears, all of which have been increased in excess proportion to the actual power required, are now in common use.

It is apparent, however, that the automotive industry has accomplished much in the direction of insisting that the drive shall be either of the geared or silent-chain type to prevent slippage, usually prevalent when machines are belt-driven. The individual motor installation has also come into common use, and at the same time the horsepower of the motor has been increased sufficiently to care for the extreme loads. For example years ago a 14-inch geared-head lathe was equipped with a ¾-horsepower motor, while to-day the machine must be provided with a motor of 2 horsepower at least and preferably 3 horsepower. This proportion may not be general for all classes of machines, but is a fair criterion of the condition at present. One of the essential features demanded in present day machines by the automotive industry is easy manipulation and the convenient location of the operating levers, handwheels and cranks. Speed and feed changing mechanisms must be located within easy reach of the operator and must not cause him any undue exertion or unnecessary delay.

Where there is a sufficient quantity of pieces and the parts lend themselves to magazine or hopper feed these must be included in order to assist in the handling of work. If the parts are heavy or bulky, mechanical or electrical handling devices must be provided in order to secure high production.

Several years ago speed bosses were practically unknown, but with the advent of the automobile era has come this type of functional foreman and with him a demand for readily obtaining in a given machine the proper speed and feed for the work. To meet this demand machine tool manufacturers have in general incorporated mechanical speed-change heads and quick change gear boxes for feed variations in their machines. Motors of the variable speed type are used when mechanical changes are not available.

Use Single Purpose Lathes.

It is interesting, however, to note certain specific conditions which, although contrary to the general demands, have worked out in the most gratifying manner. During 1912 and 1913, in a well-established automobile plant in Detroit, the production of transmission parts was receiving the most careful consideration as to the best method to adopt to materially increase their already heavy production. The concern at that time was using automatic machines of established reputation which had incorporated in them speed and feed changes, and it was finally decided, after several conferences, to adopt a single-purpose lathe having one speed and one feed, properly calculated to obtain a maximum production for each individual piece. Much to the satisfaction of all concerned the production was increased from 25 to 50 per cent. The theory in establishing a single speed and single feed was to eliminate the judgment of the operator and to predetermine the day's output. If this was not obtained the cause was readily detected and almost as readily as it had been remedied.

A very simple but most efficient method for securing quantity production is to use several arbors, some for loading while the others are working. Also, when applicable, a punch press is used for an arbor press, simultaneously loading one arbor and unloading another, this of course being used only where a battery of machines are operating on the same kind of work and call for a number of arbors of the same size, and where a conveyor is used to carry the work from the press to the lathes and return. Air cylinders and quick-action, mechanically operated chucking, or gripping devices are used wherever possible. Magnetic chucks and plates are also used extensively in various operations.

Lubrication Big Problem.

Central lubrication has been given considerable thought and study, for the seriousness of having 25 to 100 separate oil holes spread out promiscuously all over a machine is beginning to be realized. The neglect of any one oil hole invariably causes a hold up of production and may mean the entire dismantling of the machine. Therefore it becomes obvious that to control the lubrication from one point is decidedly advantageous. This is accomplished either by supplying a reservoir having gravity feed, by gear pumps delivering lubrication to the various bearings, by the use of the splash system, or by use of force-feed oilers.

The working forces of automobile factories comprise many who never saw a machine tool prior to their employment, and it is this class of help that has made it necessary to safeguard every moving part of a machine, to prevent them from getting injured. Years ago gears were left exposed and shafts allowed to run in the open, but the machines of to-day must include guards over every part that is in the least dangerous. Projecting shafts must be guarded and where it is impossible to supply guards as part of the machine, rails or nettings must be secured around the machine to prevent any possibility of injury.

The author is with the Reed-Prentice Co., Worcester, Mass., and presented this material before the recent A.S.M.E. meeting at Chicago.

SECOND EDITION.

The first edition of the Skinner Chuck Co. booklet, "Chucks and Their Uses," is entirely exhausted. We understand that a second edition is now ready for distribution. This booklet tells how to use chucks, gives illustrations of certain applications and can be secured for the asking.

Adjusting The Speed To Suit The Conditions

Different Work Must Be Performed at Various Speeds—Description of a Motor That Has a Device Which Makes The Speeds Adjustable —Mechanical Details Are Given.

MANUFACTURING conditions are always changing more or less, and naturally the problem is to approach as closely as possible the maximum output which each machine is capable of producing under ideal conditions. A change in materials, tools, or in the size of the work requires a corresponding change in machine speed. and it is in such circumstances that a variable, or adjustable speed motor is very useful.

The adjustable speed motor which we are about to describe is made by the Reliance Electric and Engineering Co., Cleveland, Ohio. Following are some details of its mechanical construction:

The speed adjustment is obtained by gradually shifting the motor armature endwise, along its axis, away from its normal position under the main field poles, this resulting in a gradual change in speed. In changing the speed the electrical circuits of the motor are not disturbed.

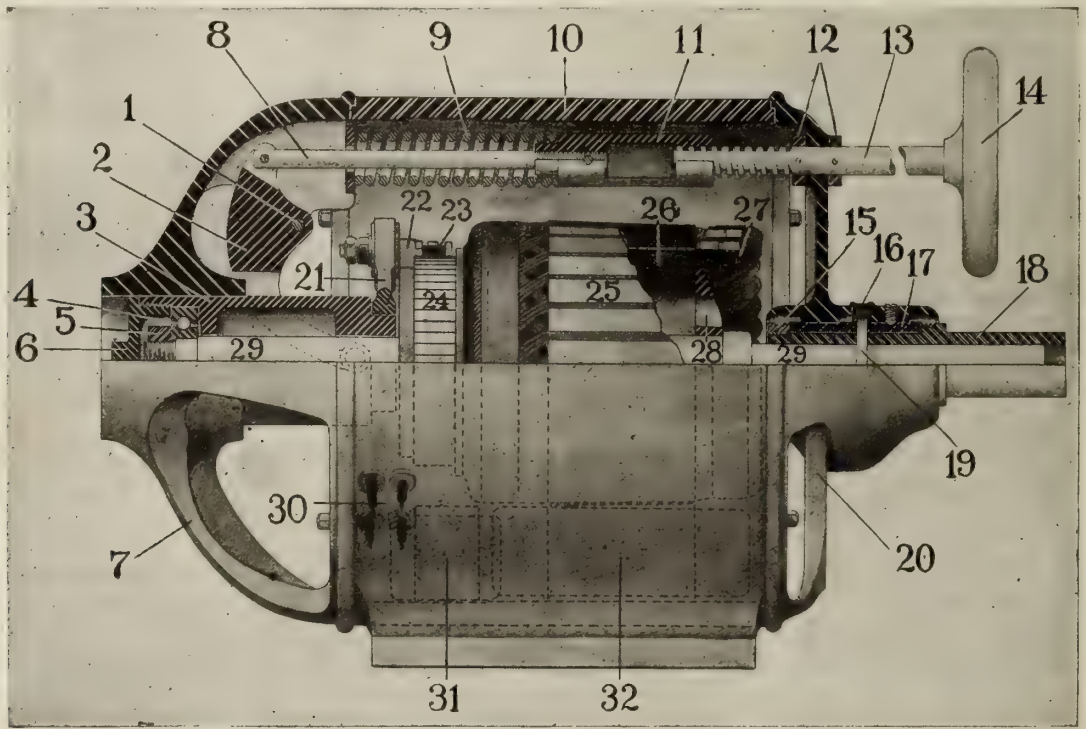
The shifting of motor armature does not alter the position of the driving pinion or pulley, so that the drive can be arranged in the same manner as with any other type of motor. With the armature in any given position, the motor practically becomes a constant speed motor, until the operator changes the position for some specific reason. The motor is said to have exactly the same horsepower capacity and will develop the same overloads with the armature in the high speed position as in the low speed position, or at any point over the entire range. The operation of starting and stopping is entirely separate from changing the speed. Automatic starters can be used if desired.

Mechanical Details.

Referring to the cross-section view, of this A. E. type as it is called, it will be noticed that the armature shaft (29) at the driving end of the motor slides within a revolving sleeve (18) on which a pulley or pinion may be mounted in the usual manner. A keyway is cut in the inner bore of the sleeve and a feather key firmly imbedded in the shaft, slides along this keyway and transmits the power from the shaft to the sleeve. The sleeve does not move laterally as the armature is shifted for speed adjustment, but is held in position by a shoulder at one end and a circular nut (15) at the other, bearing against the two end faces of the bronze bearing bushing (17). These shoulders take up any end thrust imparted to the sleeve by the shifting of the armature.

The back bearing bracket (20) is provided with an oil well, using the ordinary oil ring arrangement (19) for lubrication. The bearing bushing has spiral grooves to allow free and equal distribution of the oil, both to the sleeve and to the thrust shoulders at the end faces. The sleeve is provided with grooved oil throws to prevent the creeping of oil along the sleeve and shaft beyond the limits of the bearing box.

At the commutator end the armature shaft is supported by a combined radial and thrust ball-bearing (4) completely enclosed and protected from dirt. The inner race of this bearing is clamped between a shoulder on the shaft and nut (5) at the end of the armature shaft. The outer race is prevented from moving endwise by cap (6) and a shoulder in thrust bearing box (3). The brush yoke (21) is mounted on the inner end of this box. It is evident that any lateral movement of the sliding thrust bearing box imparts a similar movement to the armature (25) and that the thrust bearing box, brush yoke, brushes ar armature move in unison.



A forked lever (2) pivoted betwe two lugs projecting from the inner fa of one arm of the bearing bracket e gages on each side of the thrust beari box at the end toward the armatu The outer end of this lever is pinn to a short rod (8) which in turn is s curely fastened to one end of the spe adjustment nut (11). A small sha (13) on which a handwheel (14) mounted outside the back beari bracket passes through an arm of t bracket and engages at its thread inner end with the speed adjustme nut. This shaft is prevented from mo ing laterally by collars (12) both insi and outside its bearing in the brack Turning the handwheel, therefore, i parts lateral movement to the spe adjustment nut, and this, in turn, means of the rod and lever, imparts similar movement to the thrust be ing box and armature.

The number of revolutions of t handwheel required to shift the arm ture throughout the entire range speeds depends upon the frame size a speed range. This number will va from 3 turns for a 1:4 speed ratio the small frames to 16 turns for a 1: ratio on the large sizes.

The movement of the armature wi a slight turn of the handwheel is har perceptible, and it is therefore possi to adjust the speed with any degree accuracy desired. With the turning the handwheel there is a smooth, gra ual and continuous change in the spe of the motor throughout its ent range.

A special feature of the design is t use of a helical compression spring (

SECTIONAL VIEW THROUGH THE MOTOR.

Modelling Composition for Patterns

FOR some patterns it is desirable to have a material capable of being modelled while in a somewhat plastic state, nd which when hard will stand varnishing and the pres- ure of the sand when the mould is rammed up. Probably ne of the two formulae given will provide suitable material ut it must be warm when moulded, but the patterns when one with can be broken up, softened by steam heat, and ga.n kneaded and used. Take 6 lbs. of good glue, break p into small pieces and cover with water for twelve hours; ien add 4 lbs. rosin and 1 pint raw linseed oil and boil to- e'her with frequent stirrings until the rosin is dissolved.

When ready, continues "Practical Engineer," add to a ffi ient quantity of dry sifted whitening and knead together into a tough dough or putty, and while warm mould nto shape. Or, take 7 lbs. best glue and break into small ieces, then add 3½ pints cold water and boil until the lue is dissolved. At the same time dissolve 3 lbs. white osin in 3 pints raw linseed oil by heating, and then mix nd gently simmer the two solutions together for about half n hour, stirring well from time to time. Add to a sufficient uantity of dry sifted whitening as before and knead into a ough dough for moulding. Either of these compositions hen cold and hard can be rectified in shape by scraping, if e essary, the portion scraped off being, of course, saved, nd when completed the pattern or model can be varnished ith shellac varnish to resist moisture. For flat ornamental ork a composition such as that described works well, proided it is used while plastic, and with a quick worker it ssesses advantages over wax, as it can be moulded from irect. Of course, wax has to be used for some kinds of ork, particularly where there are a lot of fine details, the rocess of preparing patterns in this case being somewhat roublesome, but in such cases probably the cost is repaid y the results obtained.

Profiting by Noon Hour

THE regular method of posting information on the bulletin board is not sufficient for Dayton Engineering aboratories Co. They found that in a short time workers ost interest in this system; that a bulletin board was silent nd uninteresting; so they decided to use a lantern slide rojector as a medium to keep up the interest in efficiency.

Every noon the machine is moved to a different depart- ent, and all sorts of information is thrown on the screen, his including such matters as new construction, new deigns of apparatus, new machines, features of interest in roduction, recreational activities, products in manufacture ith an explanation as to the purposes and uses of those roducts, results and activities of the product out in the eld, athletic activities, and all other points that could posbly be of interest to the employees.

Everything shown has an educational value, yet is kept nteresting. The idea is that every worker who looks at hat slide is getting a more definite idea of what relation is work bears to the rest of the plant's work and he sees he reason for doing better work and producing more—for is own ultimate good. According to the educational diector, the company have found this scheme a decided suc- ess.

Preparing Steel for Painting

THE careful cleaning of steel before repainting has been found to be of as much importance as the painting itself. When steel is new, the rust is in light yellow spots and can be removed with scrapers made from old files turned over at the end and retempered and sharpened. Stiff scrapers and putty knives are also useful at this time. Steel brushes are not of much real value except to clean off dirt and loose mill scale.

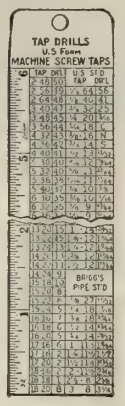
Any heavy seed rust which has formed cups down in the steel, continues L. E. Smith in a recent issue of "Factory," should be chipped out with a hammer, and the greatest care should be taken to be sure and get all the rust out of this cup so that the clear steel shows in the bottom. Care should be taken to avoid cutting the steel unnecessarily with the sharp edges of the hammer. The sand blast is a very thorough way of cleaning steel at this time, but it should be followed at once with the first coat of paint, as the surface starts to rust again very soon after the blast is used.

The tools needed for cleaning the work before repainting are about the same as for new work. Light chipping hammers are indispensable for getting off the rust scale. For cleaning the dirt off, a small bunch of broom corn wrapped with twine makes a very handy tool. After the dirt has been loosened with the broomcorn, it can be brushed off easily with the duster. This saves considerable scraping with the putty knife.

Training The Employees

THE Norton Co., Worcester, Mass., have a course for training salesmen that should interest every plant manager. Here is the plan:—

The object of the course is to prepare men for field work, as service men, demonstrators, and salesmen. The course is also open to salesmen employed by agents of the company, or to men employed by customers of the Norton Co. In this way everyone interested gets a chance.



The candidate is first examined, and if he has the proper qualifications the supervisor gives him an outline of the work involved in the training course, explains to him the rules and regulations of the department, gives him a general idea of the necessary safety precautions, and explains what will be expected of him in the line of personal contact. He is then taken through the entire plant by a competent guide, who explains the general manufacturing operations.

In subsequent talks, the applicant is told about the origin of the company, its founder, its growth, its present officers, its products, its administration and general policies, and its standing in the industrial world.

When beginning the course, the applicant is taken to the foreman of the department in which he is to work. The foreman explains the operations for which the department is responsible and the dangers to be guarded against. A competent instructor is then assigned to the student, who progresses from one department to another, the routine being the same.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

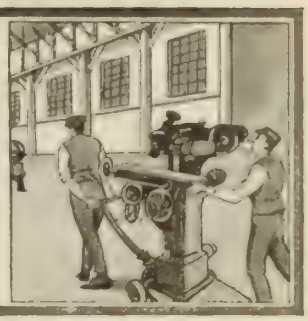
What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

There is no winner to report in this panel, as the contest was left out unavoidably in the June 30th issue. However, two prizes are being given for the July 7th contest, so watch for the results next week.

CONTEST FOR JULY 21ST ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.



1—What to do if you want speed.
2—Something to brag about.
3—Two widely different bedfellows.
4—A combination said to be ideal for I—
5—Something that will meet with insurance exactions.
6—A case where you're asked to **note** something.
7—Something that lends itself to productive ability.
8—A product said to do all you require and then some.
9—Something small for something big.
10—A product that can be made in 24 hours.
11—A case where breathing counts for something.
12—Something made in 50 styles.

Watch for the list of answers to questions in next week's issue.

Closing Date for This Contest is Aug. 11th

DEVELOPMENTS IN SHOP EQUIPMENT

CYLINDER RE-BORING MILL.

The Hinckley-Myers Co., Chicago, Ill., have marketed a power cylinder reboring mill. The cylinders are automatically set to a perfect center by means of a hardened tapered centering fixture. Adjustable cutters are used, these being easily set to size. This reboring mill will rebore any open head cylinder block the extreme over all height of which does not exceed 20 inches and cylinders from 2 13/16 inches to 5 inches in diameter. The bed of the reboring mill is only a few inches above the floor so that the motor block can be easily placed in position for reboring. The pilot bar is then lowered through the cylinder, centering in a hardened bushing in the base plate of the mill. Thus the pilot bar is held in rigid position by both bottom and top supports.

The cutter head contains three adjustable cutter blades, each blade being set independently and accurately by a micrometer gauge to the exact predetermined oversize desired. This adjustable cutter head is then mounted on the cutter tube or boring bar which is maintained in its proper relation to the cylinder by traveling over the pilot bar. The cutting bar is driven by hardened steel worm and bronze gears and double pitched spur gears. The proper speed of the cutter head is about forty revolutions per minute. The boring bar is fed automatically and is provided with an adjustable stop collar which should be previously set to stop the boring when the cutter head has reached the bottom of the given cylinder.

After cylinder block is once set in position and the boring started, no further attention is required until the operation is completed as it will automatically stop itself. In this way, the operator can be looking after other work, such as rebabbitting bearings, etc., while reboring the accumulation of cylinder blocks. It takes about five minutes to rebore a cylinder.

UNIVERSAL CHUCK.

The Karge-Baker Corporation, Phoenix, N. Y., have placed on the market a chuck for the holding of drills, dies, taps and similar tools. It is provided with a "cushioning" feature which is said to permit a moderate relative rotation between the shank and the socket ends of the chuck. A helical steel spring having a square section transmits the driving torque from one end of the chuck to the other, thus absorbing the shocks.

It is claimed that the use of the chuck largely eliminates the breakage of drills, taps and other tools, and because of the cushioning effect serves to eliminate chatter and to prolong the life of the cutting edges of the tool. It is said to act as a chip breaker when drills are used, and to provide a safety feature for such work as cutting threads to a shoulder with a die head.

The shanks and sockets can be secured in the size and style desired, and different styles are interchangeable on the chuck. The thrust is taken on double ball bearings, and an adjustment is provided to compensate for wear on the friction coil. The chuck is capable of operation in any position, and does not require lubrication. It is made in five sizes to carry drills from ¼ to 4 in. in diameter, taps from ¼ to 7 in., or die heads from ¾ to 9 in. in size.

POWER HACKSAW.

The Frontier Machine Tool Co., Inc., Buffalo, N.Y., have placed on the market a belt driven power hack saw which is provided with an automatic stop and positive clutch in the driving mechanism. The normal speed of the saw is 65 strokes per minute, while the cutting capacity is 5½ x 6 inches. Blades used vary from 8 to 14 inches in length.

NEW AUTOMATIC.

The New Britain Machine Co., New Britain, Conn., have developed a ⅝ in. by 3¾ in. six-spindle automatic screw machine which is similar in construction to the machines previously manufactured by this company. The machine carries six end-working and four side-working tools. The capacity of the chuck is ⅝ inch for round stock, 0.443 inch for square stock, and 0.542 inch for hexagon stock. The length of feed is 3¾ inches, and the length that can be milled is 3 inches.

Noiseless Gun of New Design.

In another portion of the present issue appears a detailed description of a demonstrative test on a newly invented noiseless gun. According to the story, the benefits derived from this invention will not only revolutionize war methods of gunnery, but what is more important, will simplify the process of rivetting ships, buildings, in fact any style of steel construction.

In appearance the metal gun looks like a large syringe, and in one of the tests a sharp nosed bullet, three inches long and about one-half inch diameter was driven through a steel plate ¾' in. thick. To accomplish this feat, only one-third the amount of gunpowder necessary to discharge a small rifle was used. No smoke attended the experiment and the only audible sound was that caused by the impact of the slug as it entered the plate. According to the inventor the bullet travels at a velocity of a mile a second, with a charge of only twenty grains of powder behind it.

To prove its peace time possibilities, tests were made to show its uses in steel construction. Bolts were placed in a tempered steel plate, then nuts were fastened to these bolts efficiently. The inventor claims that in rivetting, the flattening of the heads can be achieved with a single motion. Blasting operations will lend itself to this new invention, and a diver at the bottom of the Hudson River at a depth of thirty-six feet has used the device for rivetting plates. In a later experiment it required a pressure of eight tons to force the rivets out once they had been driven.

The value of such a device to the engineering trade should be world-wide. It is to be hoped that the claims extended are not mere flashes in the pan, but as the demonstration was performed before a company of distinguished engineers we can reasonably expect that the various statements made are authentic.

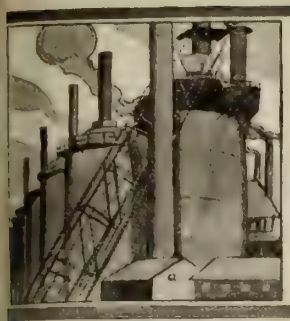
In warfare, the uses of this gun have still to be proven. Apart from the distance which such a gun will carry a projectile, it is questionable if accuracy at great distances can be secured. There are so many factors which enter into the problem that the distance capacity is not the only consideration. Even during the bombardment of Paris, during the past war, the Germans could only hope to hit the city of Paris, not aim at any particular object. The industrial advantages of such a noiseless gun, however, offset any criticism which one might offer as far as war time use is concerned.

It Pays to be Sure

THE ease with which people continue to be roped into new ventures is amazing. For example; on May 24th, upon application made to Judge Lewis at Mineola. L. I., by William H. Doolittle of Woodmere, Louis Enricht, of Farmingdale, was arrested, but later released on $1,000.00 bail. This action followed a summons and complaint made out by Doolittle who said he had paid Enricht $1.000 for 100 shares of capital stock in the Enricht Peat Gasoline Corporation.

Doolittle avers that as far back as Nov. 18, 1920, Enricht represented to him that he had organized a Corporation known as the Enricht Peat Gasoline Corporation, of which Enricht was president. Enricht, according to Doolittle, claimed he was the inventor of a process and apparatus capable of producing gasoline for ordinary commercial usage from peat such as is found in and around the village of Farmingdale and various other parts of Long Island.

This isn't the first time Enricht has come into prominence, for several years ago he announced that he could produce gasoline for 2 cents a gallon by the introduction of a green ingredient. It is said that he had leading manufacturers of cars at his place, these including Henry Ford, but up to date nothing has developed in the green gas proposition.



Why didn't these manufacturers take hold of the green gas idea? Simply because their knowledge told them the scheme wasn't feasible. Two cent gasoline would be a boon to the country in general, but like the peat scheme, the idea is still a theory.

When investing in any new venture it pays to make sure the idea is practical, not merely a dream of the inventor. Inventors generally see their idea in its very best form. To them obstacles do not exist. Listen to their claims by all means, then use your mechanical knowledge in arriving at your OWN decision. Should you still be undecided, consult some authority on the subject. Better lose a little money on good advice, than a large amount on a foolish venture.

A Move in the Right Direction.

The representatives of the building trades in Toronto made a wise move the other day when they passed a resolution in favor of accepting an all around wage reduction of 10 cents per hour. After a spirited controversy they decided to take this resolution to their respective unions, and it is to be hoped that the various bodies interested will follow up the good work, voting favorably on the resolution.

There is no question but that the cost of living has come down sufficiently for the building trades to accept such a small reduction. If building activities are to be stimulated such a move is imperative, but reductions should not be confined to wages alone. Materials in general should sag accordingly, and in some cases they have already dropped. Once let the building trades get down to a good solid foundation, and building will once more boom, giving employment to many who are at present in pretty poor circumstances. If the present motion goes through the reduction will become effective July 25th. For the good of Canada, let the leaders of the various unions see to it that no obstacle is placed in the way.

MARKET DEVELOPMENTS

Can't Get Any Worse—So Must Get Better!

That Seems To Be The Feeling In Some Of The Steel Centres—Lower Prices Not Likely To Bring More Business Into the Market under Present Conditions.

PITTSBURGH seems inclined to the belief that the turn in the steel situation must come very quickly, and that it must be for the better simply because things cannot get any worse. This may be a negative way of reasoning the matter out, but there is some slight evidence brought to bear on the point too. For instance some of the mills report a little better inquiry from sources that should take on quite a tonnage once they come into the market definitely.

The Canadian trade is inclined to argue that the prices of steel will make very little difference in the present market, as the business that is coming is almost certain to be placed regardless of price. One dealer quotes a $400,000 school contract placed a few days ago, showing that the steel in the place will run only $7,000. His conclusion is that prices of other lines must come down in order to loosen up building.

The machine tool market is doing little business, and the chances are that most of it is coming from the woodworking concerns, as they are doing more buying than the metal working industries.

Scrap metal markets continue inactive at nearly all points, and prices are not standard, being simply a matter of arrangement and bargaining between buyer and seller.

WILL OPERATIONS CONTINUE AT EXTREMELY LOW FIGURES

PITTSBURGH, July 21.—It is easy to guess wrong, but a perfectly rational guess is that the turn in the steel situation has come. There is no actual improvement to speak of, though some mills report a wider distribution of inquiry and a somewhat larger total volume of inquiry, while others report practically no inquiry. The chief point in the argument that the turn has come is that the steel situation could not grow any worse. If it could grow any worse it would have done so already, since it has been trying to do its worst for several weeks. There was not only the most complete absence of requirements that could be conceived, but also the strongest disposition on the part of those who did need material to postpone purchases because they did not have confidence in prices, which had the semblance of being maintained at arbitrary levels. Now that appearance has largely disappeared, for there is a strongly competitive market. The buyer may not be quoted as low a price as he would like to receive, but he can see that there is competition for his business. The common asking prices are those formally announced earlier in the month, but these prices are subject to concessions. Some mills will quote the full prices, but they will not do this, as usually they have done, on account of a feeling that they have a duty to maintain the market. They will adhere to the asking prices, if they do so, simply because they do not want to accept less, and that will make a decidedly different impression upon the buyer.

Mill Operations.

It is impossible to estimate with great closeness the rate of steel production, but there is no ground for estimating the rate at higher than 20 per cent. at the outside. One observer sets the rate at 15 per cent. The last report as to the Steel Corporation showed it at a 25 per cent. rate, at the end of June, and a rate a trifle below this was probably reached in the first few days of July. The independents are not operating at as much as 15 per cent., and possibly at not as much as 10 per cent. The balance of probability is that the rate for the whole steel industry is at about half way between 15 and 20 per cent. There is no evidence, however, that the rate has decreased any in the past week or ten days, and there is therefore basis for believing that the low point has already been reached. This means perforce that the next change in the operating rate will be an increase. It is the easiest thing for steel production to increase, and very difficult for it to decrease farther. For illustration, one of the largest of the independent steel plants has not made a ton of steel for three weeks.

Classes of Buying.

Buyers of steel may be divided into four general classes, jobbers, manufacturing consumers, railroads and builders. In the past few weeks there has been a little buying, a very little, by each of the four classes, the railroads making the lightest showing of all. There has been some speculation as to which line would first show improvement when any improvement at all should come. Some mills now pick out building as the line which shows the most marked improvement now. This would be contrary to a theory entertained in many quarters, that the demand for steel as a whole has been subnormal, below the actual consumption, so that the first increase in buying would come from those who should run out of steel. Jobbers and manufacturing consumers are always selling something and have been in process of liquidating stocks, while the railroads even if indisposed to buy must take something from time to time as they are still operating. Railroad traffic is only a few per cent. below the rate in the best year before the war. Builders, on the other hand, could wait an indefinite period. Nevertheless, there is the experience of some steel interests that the plainest improvement in demand now is in the line of construction work. This might be due to the widespread unemployment. It is said that wages in the building trades have not been liquidated or adjusted, but it is also re-

marked that the building trades unions have their scales but the scales are doing them no good. Work is being done by nonunion labor, or by workmen who have union cards tucked away at home and are working for what they can get and as hard as they can, hoping the "business agent" (who was called "walking delegate" until he took the automobile) won't see him.

Prices.

There is a regularly competitive market in steel products in general. In an occasional product there may be no regular competition, but the rule is competition. Some mills may not be competing in price, but enough ore to make a decidedly competitive market. The price may not entirely suit the buyer's preconceived ideas, but at any rate he can see that his business is being sought after on a price basis.

In general, though there may be exceptions, the actual market in a given commodity is some concession, more or less according to the attractiveness of the order, from the regular or nominal asking prices, which are: Billets, $33; slabs, $34; sheet bars, $35; rods, $42; bars, 1.90c; shapes 2c; plates, 2c; blue annealed sheets, 2.65c; black sheets, 3.50c; galvanized sheets, 4.50c; tin plate, $5.75; hoops, 2.60c; wire, 2.50c; nails, $2.75; painted barb wire, 2.90c; galvanized barb wire, 3.40c; cold rolled strips, 4.25c; cold finished steel bars, 2.80c.

Plates show the widest and most general divergence from the asking price unless that honor should be given to galvanized sheets. An ordinary order could probably be placed at 1.90c, Pittsburgh, for delivery nearby. In the east and west there is a wholesale ignoring of the Pittsburgh basing, prices f.o.b. Chicago or Eastern Pennsylvania mills being little if at all above prices f.o.b. Pittsburgh mills. On Pittsburgh basing, a price of 2c, Pittsburgh, would mean 2.35c, Philadelphia, and 2.38c, Chicago, but an order sufficiently attractive to bring out a price of 1.90c, Pittsburgh, for delivery in this district, would bring out prices much below 2.28c, Chicago, or 2.25c, Philadelphia.

Pig Iron.

The local pig iron market has worked off another 50 cents a ton. prices at valley furnaces now being: Bessemer, $21; basic, $19.50; foundry, $20.50, with $1.96 freight to Pittsburgh. In the case of basic there are offerings for Pittsburgh delivery by producers having much less than the valley freight at 50 cents or more below the valley equivalent, that is, $19.50 valley would be $21.46 delivered Pittsburgh if one bought valley iron, but one can get iron elsewhere at less than $21.46 delivered Pittsburgh, perhaps at about $20.50.

Connellsville furnace coke for spot shipment is weak at $3. Foundry is quotable at $4 to $4.50 according to brand and is selling very slowly, particularly brands held at above $4. The Wickwire-Spencer Steel Company, Buffalo, has inquired for 15,000 tons each August and September of Connellsville furnace coke, having in mind to start a blast furnace if the operating cost can be gotten down far enough.

POINTS IN WEEK'S MARKETING NOTES

According to reports the production of steel tube is lower than it has been for many years. There is little demand for heavy lap weld material. Building stagnation is holding back the buying of standard merchant material.

Coke shows slight signs of improvement, and raw coal output is beginning to gain. There is less difficulty in finding consumers for Connellsville coal than there is in locating buyers of coke.

The steel and scrap iron market in Chicago is very dull. The humdrum routine of trading continues, this being chiefly confined to dealers. There is very little consumer buying, this being confined to the purchasing of immediate needs.

The old metal market in New York presents no changes. The market is quiet with few enquiries. Scrap copper is the only metal stirring, and this movement is nothing to boast of. Zinc scraps are the weakest of all.

The pig iron market at Pittsburgh remains quiet. There seems to be a slight buying movement but nothing of real importance. A few enquiries for Bessemer are being received, and quotations remain around $21.50 to $22.00 valley. The volume of business, however, is no real test of the market.

Plate business in Philadelphia is better than usual, although other markets report no noticeable improvement. Railroad repair work is creating some business, otherwise nothing of importance can be recorded.

The recent price reduction on bars seems to have had a good effect as enquiries have been quite a bit better. Many of these enquiries have led to actual orders. It is expected that as time goes on this branch of the industry will improve considerably, but as dealers state: "One cannot expect any sensational improvement immediately."

In practically all markets, scrap is reported as very dull. One dealer says that industries as a unit are out of the market so far as purchasing is concerned, and that dealers are confining their operations to picking up bargains for storing or covering short contracts. Prices still seem to point downwards.

LOWER PRICE OF NO USE JUST NO

Dealers Hold That Business Cannot Brought Into the Market in This Way.

TORONTO.—The markets for ir steel and machine tools have be regular hot weather affairs during t week. There is very little business ing done, although one finds here a there dealers who claim that they h very hopeful-looking inquiries, but t have not booked anything very subst tial in the way of real business fr these prospects yet.

There is very little talk of lo prices in any of the lines, for the v good reason that the dealers seemed clined to the view that lower pri would not stir up any more business.

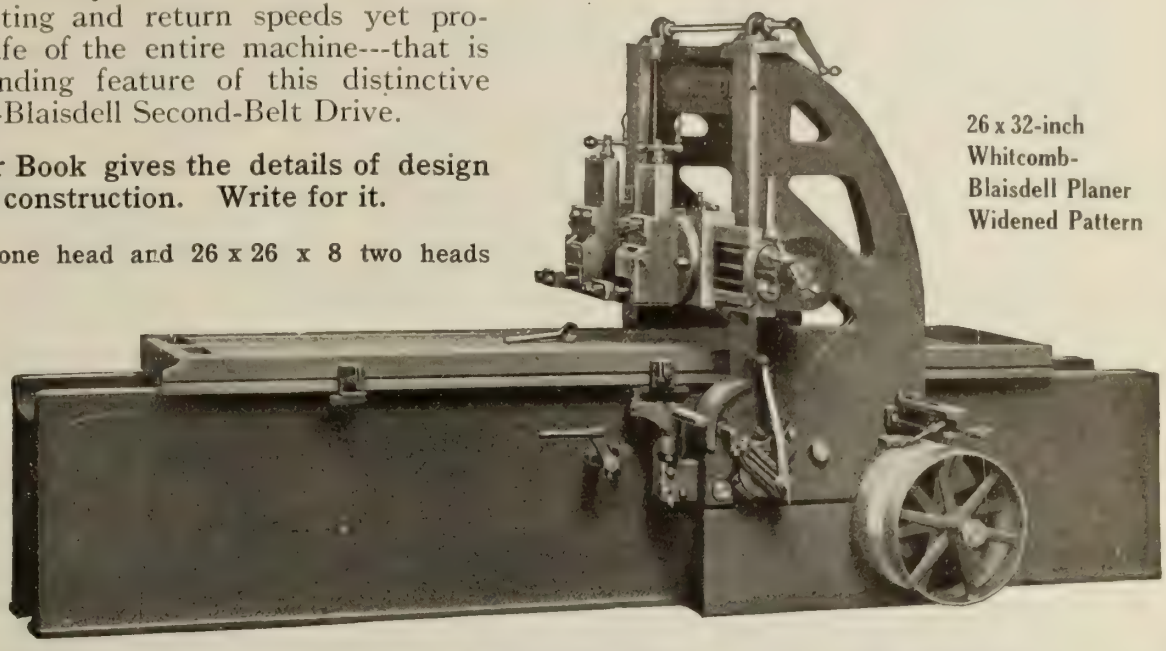
Machine tool builders for the m part are not busy, some of the pla being down in several departments. C adian representatives of United Sta firms also report that word they rece from their principals tells of quiet ti in the building of tools. The few m chines that are going through have bear the overhead, which in most ca is still high, and will likely stay up, for this reason it is hard for prices to brought down in the face of these pr pects.

Wood-working Better.

Firms handling both metal and wo working machines claim that the f mer is bringing the greater amount their business for the present, altho orders are coming through in s quarters for the metal working tools.

Two firms this week mentioned fact that with them collections w showing some improvement for the f time in several months. One of places in particular had a number of counts that had for some time cau difficulty.

The Steel Market.



"There is too much being said ab the prices of steel being likely to dro claimed one steel dealer. "We hea all the time, and the statement is of made to us that building is not be proceeded with because the price steel is too high. I don't believe tha the price of steel were cut in two to it would sell another hundred tons. H are some of the figures that show t steel is not a very big item in m

The Planer with the Second-Belt Drive

A smooth, easy reverse --- which permits higher cutting and return speeds yet prolongs the life of the entire machine---that is the outstanding feature of this distinctive Whitcomb-Blaisdell Second-Belt Drive.

Pages 60-61 Are for You

THE K–T FOUNDRY GALT, ONT.

TRADE K–T MARK

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

buildings. In one school building that costs $400,000 the steel is worth $7,000, and in another job of $235,000, the steel is worth $10,000. There are a whole lot of other things that must take a drop too. As far as prices go, we cannot see where any good purpose would be served by cutting into them now. The business that is coming into the market is all for quick shipment, and there is very little being bought for future use. One might say very truly that the orders that are coming are placed regardless of cost because the steel has to be secured, and we might as well get three dollars more than three dollars less. When buyers show a tendency to take hold and buy more heavily there may be something done about prices, but not before."

Another office reports that they are getting from four to five hundred tons ordered per week, all for immediate shipment. The buying of this seems to be very general, and it can hardly be said that there seems to be a preference for any particular class.

Small Tools Are Slow.

Little business is being done in small tools. Prices are not holding any too firm in several places. Some of the dealers claim that buyers are getting supplies at figures which they cannot meet and make a living profit." I know of plants that used to carry a stock that would start a man in business, but today they have not enough in their place to keep the shop going. This is possible because operations are being carried on at a low ebb. Some day these shops are going to be busy again, and there is bound to be some good business handed out."

The Scrap Metal Market.

"Things are just the same in the scrap metal markets as they were two weeks ago or two months ago." That is the way the situation was described this week. This dealer added that there was only a small amount of business being done. Contracts are not being made as neither dealers or buyers feel any certainty of present values. The figures involved in sales represent in most cases less than the intrinsic value of the metal but that does not cause buying for the purpose of piling against future requirements.

Scrap Metal Markets

St. Louis reports that there is absolutely no change for the better. As they say, "Industries as a unit are out of the market so far as purchasing is concerned, and dealers are confining their operations to picking up bargains for storing or covering short contracts."

As far as can be noted the price tendency is still downward. From reports it would appear that less agricultural scrap has been collected this year than in more than a decade. Low quotations and high freight rates have practically squashed the scrap business.

In Pittsburgh the market is of the hand to mouth variety. In New York the prices have again dropped a little. On some materials, such as borings, turnings, etc., the dealers are actually offering less than the freight charges to point of consumption. Naturally, very little business is being done.

In Buffalo, it is said that the mills now in operation are so well supplied, that little buying is looked for. Cincinnati and Chicago both report a dull market; in fact the scrap market can be likened to the very hot man who weakly gasped, "I'm almost dead."

Pig Iron Markets

In Philadelphia the pig iron market is rather weak. Following the break of last week, the recovery has not been what was hoped for. Buyers are few and far between, and no immediate recovery is expected.

Chicago reports a slight increase in orders, but none of these are of large tonnage. New York and Cleveland speak once more of declining prices with a soft market and the same light buying which has existed for months. A better feeling seems to exist on the latter market and some producers who believe that the lowest possible point has been reached look for an early improvement.

Pittsburgh market is still light. On the surface there is an indication of a buying movement but not of any great proportions. A few enquiries for Bessemer are being received, but not enough to count.

In Boston and Cincinnati prices are again lower. Practically all orders coming into the market are accompanied by requests for shipment at once. This proves of course that purchasers are buying for immediate needs only.

TRADE GOSSIP

Stainless steel spoons and forks are now a commercial possibility. This is the result of over a year of experiment, and the finish in each case is said to be excellent, the varnishing being done by machinery.

It is claimed that there is no risk of stain or tarnish, and that both spoons and forks will retain their polish so long as no unnecessary cleaning materials are used. Like the stainless steel table knives, only ordinary washing and wiping are necessary.

In order to stimulate the machinery and machine tool manufacturing industry, the Japanese government is preparing plans to hold a machinery and tool exhibition at Osaka, Japan, some time in October.

Before the war the manufacture of tools and machinery in Japan was very light, but during the war the industry grew considerably. Since 1919 the industry has been on somewhat of a decline, and it is this condition that is spurring the Japanese government on to the decision to hold the exhibition.

They are said to realize that a powerful incentive is needed to prevent the collapse of the new found industry. The exhibition will be under the direction of the department of agriculture and commerce, with the cooperation of the army, navy and census bureau, and will include machine tools, small tools, motors, materials used in the manufacture of tools and grinding machines, etc. According to present plans, prizes will be offered for models and designs.

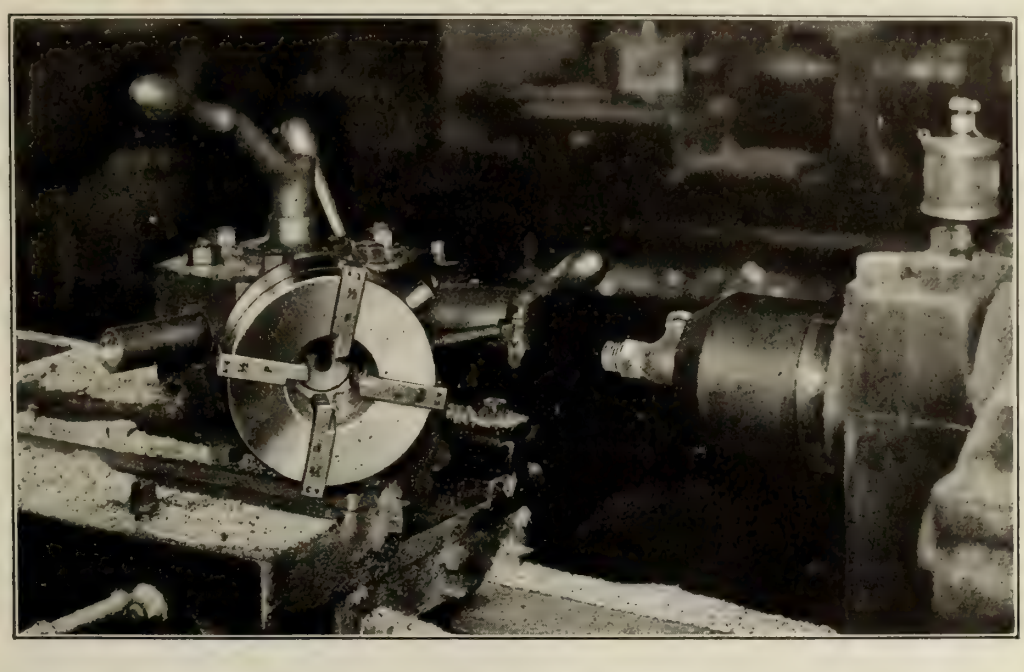
Mr. W. McL. Clarke, Canadian Trade Commissioner in Milan, writes that following on representations made, the recent concession to the United Kingdom by the Italian Government, under which it is no longer necessary to obtain a license for the importation of motor cars from that country into Italy, has been extended to Canada, and restrictions regarding the importation of Canadian motor cars have been withdrawn.

Extensive improvement plans are going to be made by the Jamaican Government to the harbour at Kingston. The cost will be in the neighborhood of $5,000,000, and it is hoped that these improvements will attract the ships passing through the Panama Canal. Vessels from New Zealand, Australia, Tasmania, and the ships of the Canadian Covernment Mercantile Marine coming to Jamaica have been exempted from tonnage and lighthouse dues from 1923 to 1923, inclusive.

The Town Council of Kingsville, Ont. intends making extensions and improvements to their water works. It is expected that the changes will cost in the neighborhood of $15,000.

Plans for several steel highway bridges for Edmonton, Alta., and locality, are made, and tenders on these will be received until July 30th, by J. I. Robertson, the Deputy Minister Dept. of Public Works, Provincial Govt.

The London and Port Stanley Railway Board are planning the construction of three railway sidings, which will cost around $20,000.



George Hibbert, 195 Jarvis St., Toronto, intends building a garage which will cost approximately $13,000.

An addition to a hotel for the Northern Hotels Co., Toronto, is being planned. It is expected that the work will cost about $700,000.

NOISELESS GUN FOR RIVETING STEEL

New Invention Which Has Both War and Peace Time Possibilities. Inventor Uses Charge of Gunpowder for Blow. Demonstrations Given Before Company of Engineers.

A new noiseless gun, with both war and industrial possibilities, has been invented and demonstrated by Dr. Miller Reese Hutchinson. In his laboratory in the Woolworth tower in New York, he demonstrated before a company of distinguished engineers the gun's possibilities.

Dr. Hutchinson, in the presence of many distinguished engineers, using a metal gun device no longer than his arm and looking like a big syringe, drove through a steel plate three-quarters of an inch thick a sharp nosed bullet three inches long and about one-half inch in diameter. In doing this, he said, the quantity of gunpowder used was only one-third the amount burned in discharging a small rifle. There was no smoke attending the experiment and the only audible sound was that caused by the impact of the slug as it penetrated the plate. The bullet, the inventor said, travels at the velocity of a mile a second with a charge of only twenty grains of powder behind it.

Penetration Regulated.

Dr. Hutchinson, using his right arm only held the gun of syringelike appearance directly against the steel plate, which was set across an ordinary wooden box filled with what appeared to be sawdust. The release of this almost incredible power and velocity seemingly was effected by a slight downward push such as might be used in emptying a large metallic syringe and it was attended apparently by no recoil such as would be felt from an ordinary gun. For wartime use enlarged guns of this type, Dr. Hutchinson said, could be made to throw five ton gas shells for miles.

The degree of penetration may be regulated by the size of the charge and the penetration of the slug may be stopped at the will of the operator. The inventor shot through the plate rows of bulletlike slugs the bottom half of which had been threaded like a screw. He caused the missiles to stop exactly where the threaded portion of the slug —or rivet—impinged upon the lower surface of the plate. Then, to demonstrate the utility of the device in steel construction, he speedily adjusted screw nuts to the dozen or more bolts he had shoved through the tempered steel in perfect alignment. He then tightened up the nuts.

Dr. Hutchinson said in steel construction, the flattening down of the rivet heads would be achieved with the single motion that drives the rivet through the steel plate—that is, by the simple discharge of what in its application to war will be a new weapon, soundless, smokeless, and of tremendous penetrative power. The device also, he said, will be of vast value in blasting operations.

"As a matter of fact," he claims, "this principle, which is a new one in ballistics, discovered by Robert Temple of England, was primarily developed under the stress of the war. Its application to the peace industries is what interests us principally now, and it is not difficult for you to see how this little device may eliminate the nerve racking din attending the hammering of the pneumatic rivetting machines now used on all steel construction, besides vastly simplifying the process of rivetting plates with great economy of time and effort.

"This device can be used under water I had a diver take it down to the bottom of the Hudson River and there, at a depth of thirty-six feet, it drove its rivets perfectly and they were so tightly inserted through the three-quarter inch plate that it required a pressure of eight tons to force them out once they had been driven. This suggests great utility in the speedy repair of shattered vessels."

IDEAS WANTED.

We are particularly desirous of obtaining for this section of our journal, short instructive ideas. These can cover any phase of machine shop practice and should be illustrated if possible by a sketch of the idea being described.

If you are unable to make a neat sketch, do not let that stop you. Draw the idea as best you can, send it in to us and we will finish it up for you. For all accepted material we pay a good rate, so that not only do you help some one else by passing along the idea, but you benefit yourself as well.

This section should be a regular exchange of ideas. Surely Canadian mechanics have many schemes that have saved them both time and money. Send them to the Editor of Canadian Machinery, 143 University Ave., Toronto, Canada. Don't be a once in a while contributor. Become a regular. You'll find it pays.

STEEL INDUSTRY NOT VERY ACTIVE

According to a report issued by the American Iron and Steel Institute, the production of steel ingots in June by 30 companies, which in 1920 produced 84.20% of the total output, was 1,003,406 tons made up of 808,286 tons of open-hearth, 193,644 tons of Bessemer 1,476 tons of all other steel. Upon this basis, all of the steel companies produced approximately 1,100,000 tons of ingots last month, against 1,360,000 tons in May and 1,297,805 tons in April. The U. S. Steel Corporation which operated at an average of 32% in June produced about 600,000 tons of the total and independent companies, whose operations averaged about 18% of capacity produced approximately 500,000 tons. The industry as a whole operated throughout the month at an average rate of 24.13% of capacity.

During the second quarter of the year, the 30 steel companies reporting to the American Iron & Steel Institute produced 3,479,808 tons of ingots against an output during the first quarter of 4,911,736 tons. The total output for the first six months therefore was 8,391,544 tons. All of the steel companies in the second quarter of the year produced 3,757,885 tons, against an output of 5,870,000 tons during the first quarter. The total output of all companies during the first six months

Vancouver, B. C.

of the year therefore was 9,627,885 tons.

To-day, of course, operations of the various steel plants are the lowest since January, 1908, and compared with capacity, the lowest of record. The industry as a whole has not more than 20% of capacity active but the Corporation is operating probably close to 25% of capacity.

NEW CATALOGUES

The Davis-Bournonville Co., Jersey City, have issued a revised circular covering their acetylene generators, welding and cutting torches, portable outfits, and welding supplies.

The Electric Hoist Manufacturers' Association, New York, have issued two circulars dealing with their different lines. One book is devoted to approved applications, the other to monorail runway construction. Both circulars are well illustrated and contain interesting data.

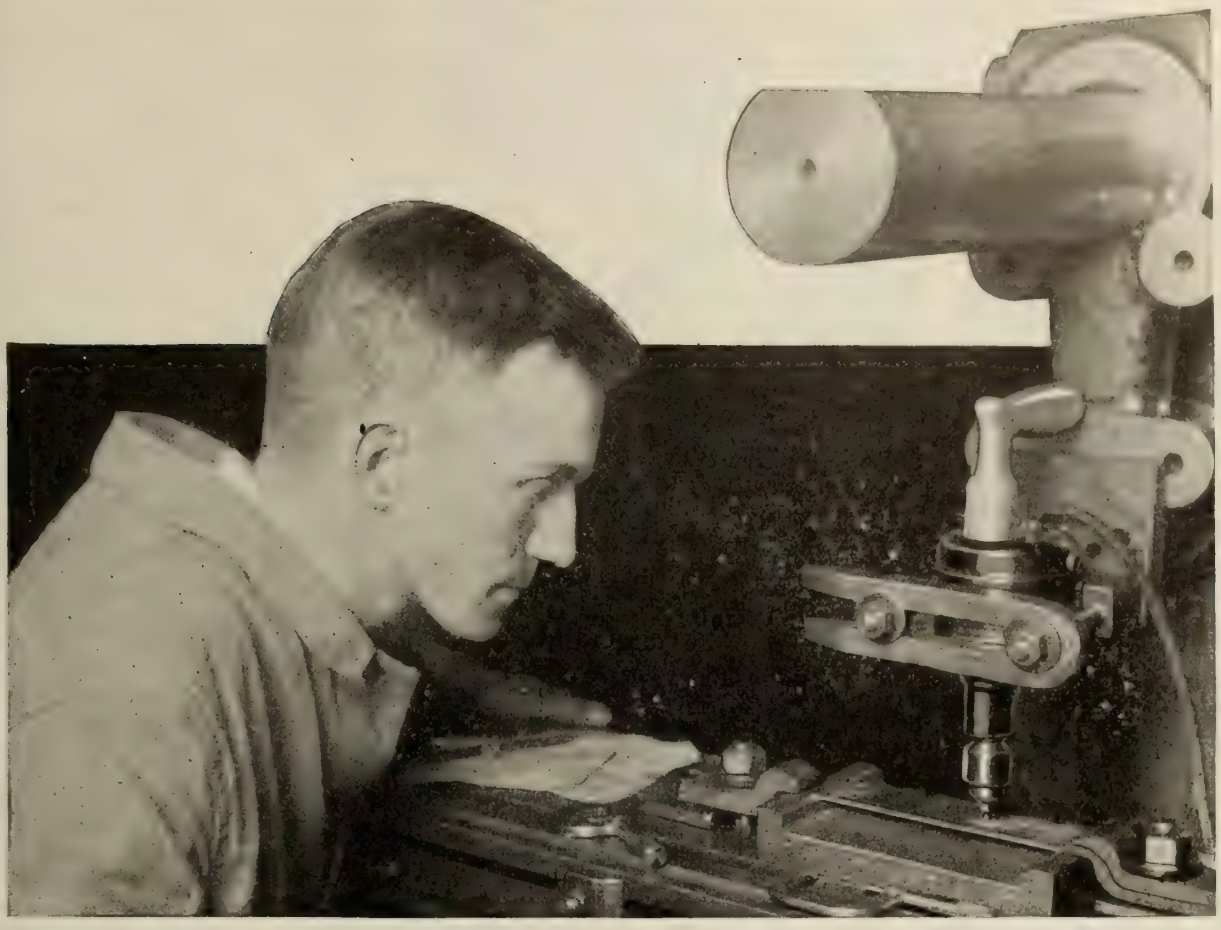
The Oliver Machinery Co., Grand Rapids, Mich., have sent us data on their pattern milling machine. This is in circular form, and should be of interest to anyone engaged in such work.

The Canadian Ingersoll Rand Co., Sherbrooke, Que., with general sales offices in Montreal, have forwarded us a very complete catalogue on pulp and paper machinery. It is in loose leaf form, consisting of sections under the following heads: The Ryther Slasher System; Pulpwood Barking Drums; Paulson Patent Bark Press; Ryther Reciprocating Chip Screens; Parallel Endless Chain Log Haul, and Bird Auxiliary Screens. The matter is well prepared and of decided interest.

We have received a book from the Swedish Chamber of Commerce of the U.S.A. Produce Exchange Annex, New York, entitled "Iron and Steel in Sweden." The book contains over 200 pages and is profusely illustrated. The work preparing this volume must have been enormous, for the data contained is accurate and reliable. The idea of the book is to give the necessary information to buyers of Swedish iron and steel. To anyone interested, we can recommend a perusal of this interesting story of steel.

The Sir W. G. Armstrong Whitworth & Co., Ltd., Westminster, England, have forwarded us various catalogues dealing with the following lines. Twist Drills, Pneumatic Tools; Screwing Apparatus; Standard Gauges; Tool Steels; Types of Warships and Mercantile Steamers; and Commercial Products. All these books are well illustrated and contain considerable data of value. In addition to the above this concern forwarded a book covering the war w of their firm, which in itself is a w derful story of achievement.

The Shurly-Dietrich Co., Ltd., G Ont., have issued a supplement to th main catalogue, this new book conta ing the new list prices. Their regu lines of saws are illustrated throughc



The A. R. Williams Co., Montr have issued a Machinery Bulletin, 2151, which shows clearly the vari lines which they handle. Many ill trations are used, and full data on various machines is given.

HOPE FOR DEVELOPMEN OF EXPORT TRADE

The Canadian section of the Bri Chamber of Commerce in Paris is tively engaged in a movement for development of trade between Can and France. The Hon. Secretary, W. H. Dorey, has for the past months been quietly working among manufacturers and exporters poin out the advantages there are for the port of Canadian products to Fra and the central countries of Eur Mr. Dorey advises manufacturers others desirous of opening up trade lations with the Central Euro countries such as Serbia, Roumania Czecho-Slovakia, to do so through Pa which is the most important finan centre and which controls wide in ests in those powers, which, as m people are aware, comprise the for State of Bohemia, and other le States of the disintegrated Austrian pire.

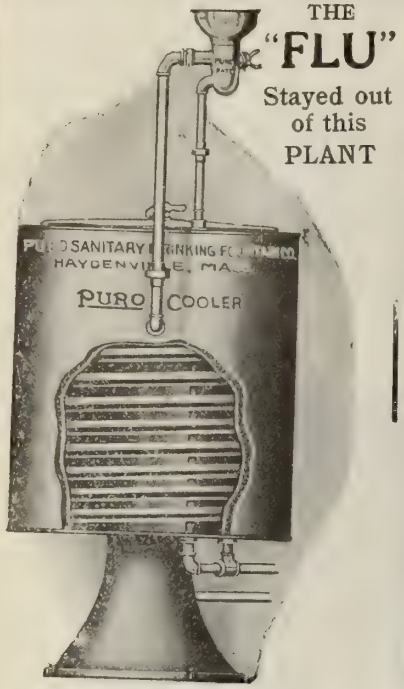
Support Given.

The movement has the support of Board of Trade, Canadian Manufac ers' Association, and a large and fluential number of mercantile financial concerns in the city. All C dian business men are invited to in est themselves in the movement through its agency a vast and profit market for Canadian products wil opened up. The main feature for manufacturers thinking of develo an export trade to consider is tha carefully studying the requirement the foreign markets and to see that products comply with same. Thi most essential for the building up remunerative export business. Inqu regarding the new markets and t openings are cordially invited by Chamber, which will furnish the fu and most reliable information pos free of cost. Communications shoul addressed to Mr. W. H. Dorey, Secretary, Canadian Section, Br Chamber of Commerce, 6 Rue Ha Paris, France.

Yankee Ingenuity Solves Drilling Problems with the Aid of this Dumore High Speed Drill

John Bath & Company, Inc. (Worcester, Mass.)—maker of fine tools—uses a half dozen each of Dumore Drills and Grinders in his up-to-date shop.

The Photograph shows a Dumore Drill mounted on the overarm of a milling machine drilling holes in a tool steel jig plate ⅛″ thick. There are 76 holes spaced .080″ apart in several rows and a drill .051″ in diameter is used.



Dumore Drills—like the well known Dumore Grinders—are accurately built, with an almost unlimited range of application. Used to supplement the work of big machines, Dumore High Speed Drills add to the capacity of the shop and cut production costs on many classes of work.

Send for the details of Dumore High Speed Drills and Grinders. Let us show you how you can use them to advantage.

UNFILLED ORDERS REMAIN ON BOOKS

5,117,868 Tons Remain on Books of Subsidiary Companies—Operations in June Averaged 32% of Capacity.

According to the monthly statement of the U. S. Steel Corporation, there remained unfilled, orders on the books of the subsidiary companies, to the extent of 5,117,868 tons. This shows a decrease of 364,619 tons during the month. Since the first of the year the unfilled tonnage has decreased over 3,000,000 tons. The corporation operated its plant in June at an average rate of 32% of capacity, indicating an output of 607,000 tons of ingots and 456,000 tons of rolled products. Shipments of finished steel are estimated at 450,000 tons. Orders booked during the month averaged a little less than 7,000 tons a day, making a total of 175,381 tons, the smallest bookings in any month since before the war. The indication is that there were cancellations of about 90,000 tons and with that exception shipments exceeded business by 274,619 tons.

To-day they are operating at not much over 25% of capacity and unless the new schedule of prices has just been put into effect develops new business of importance, the outlook is not very encouraging for the near future. In the second quarter of the year, that is, in April, May and June, the Corporation produced approximately 2,133,792 tons of ingots and 1,601,092 tons of rolled products. Shipments are indicated to have been 1,550,000 tons and the total orders taken, 618,459 tons. It is quite evident that the second quarter earnings were very unsatisfactory, but fortunately they have a large surplus upon which it may draw to meet dividend requirements.

The new schedule of prices, of course, did not go into effect until the second quarter was ended, but many of the lower prices recognized officially last week were already current during the latter part of June. The lower wage scale of the Corporation which results from its abrogation of the basic or overtime day did not go into effect until July 16th. This abrogation is equivalent to reducing wages 8½% to 14%.

ADJUSTING THE SPEED

Continued from page 44

to counterbalance the magnetic pull of the fields and armature. This magnetic pull tends to return the armature to its normal position beneath the poles and is greatest just as the armature is leaving the pole pieces, gradually decreasing in value from that point as the air-gap is lengthened. The spring is compressed between a seat on the inner face of the front bearing bracket and a shoulder on the speed adjustment nut. The lever rod passes through the helical spring. It is evident that the spring is brought into the greatest compression, exerting its greatest counterbalancing, as the armature approaches its normal position under the main poles. By a careful proportioning of the different parts, satisfactory adjustment of the two opposing forces is obtained for all positions of the armature, making easy and simple the shifting of the armature for speed control.

These motors are made both in the open, and fully enclosed dust proof type.

CASTING TROUBLES

Continued .rom page 42

dred 1,200 lb. castings per year. Their grey iron department could take on more work and they quoted a 5 cent price against the 6½ cents we were paying elsewhere and agreed to make their own pattern. They were a big concern and evidently knew all about the business, so we contracted at once. We stipulated that the castings were to be delivered one side up and that a sample casting should be sent for us to try out in all particulars. Three months later, the freight office notified us that a car had arrived loaded with castings from this company.

We got two of them trucked in at once and put one on each planer. That was enough to run us two days and the truck was to unload the rest on the morrow. They were the nicest, cleanest, straightest looking castings we had ever seen and we congratulated ourselves on having struck a real foundry at last. Just then Jimmy came up to say he couldn't drill the holes for the finger clamps. He was given a new drill and finished presently. An hour later, Steve, the planer hand complained of the castings—said he had used six good H. S. bits already and hadn't cut two inches across.

Those castings arrived about two years too late to be used in the war as bullet proof armor plate. We didn't unload any more but phoned the N. Y. office and a representative came right up. He spent two days trying to chip test the castings and then gave it up. Our dream had faded over night. Instead of following instructions and sending one casting to be tried out, they went ahead and made a big lot of them —while we waited. That deal cost them over $3,000 and lost them a steady business. The N. Y. man was pretty cute. He had the castings taken out of the car and trucked down to the other freight station, returning them by the Central Ry. There were a dozen cracked castings in the lot and he made claim for these on the score of mis-handling (thus the railway paid for a part of the loss, which was no more fault of theirs than if the parts had been so much glass shipped unpacked).

It has been said that the automobile business has taken the best iron and the best foundry workers. Maybe that is so. In our case, poor castings lost us $6,000 last year and yet the foundries act insulted at the return of a single piece. There exists a widespread belief that only in those plants where they machine their own castings is there any care taken of the work in the foundry. I used to make an occasional suggestion to one foundry superintendent and it never got any further than his stock question, "You're not a moulder, are you?" Moulding is a trade that is just as susceptible to human skill and study and care as is any other—there's something radically wrong with either the men or the equipment to let them turn out such a low grade product—a machine shop could not turn out a single piece to the same standard.

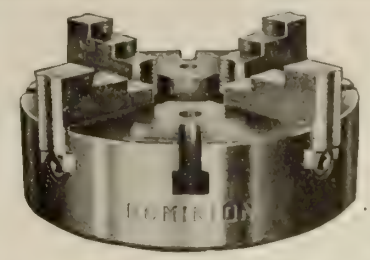
'OUTHS SHOULD BE TRAINED TO EFFICIENCY

Speaking on "Canada's Interests rom a Business and Citizen Point of ew," Dr. Cody, aired a few truths that e well worth repeating. He said in rt: —

"What has enabled Germany to recov- so rapidly from defeat and once again ve signs of becoming one of the most rmidable competitors in the world's arkets?" he continued. "The German orkman to-day is willing to work - id work efficiently- at a lower wage an the workmen of Great Britain and her countries. Technical education ays a big part in the development of e commercial interests of Germany. though still suffering from the knock- t blow delivered by the troops of the lied armies, Germany has established ousands of technical schools through- t her empire for the better equipment her workers, so that they may become illed and competent to do the best rk.



"This can be accomplished in Canada ly by training our youths in a Do- nion-wide system of secondary tech- al schools. The idea that should oc- py first place in the minds of our edu- tionalists is that the Canadian youth all be as well trained technically and iciently as in any other country in the rld. The Dominion Government by a thod of subsidizing has succeeded in ablishing technical schools in the dif- ent provinces."

A SOLID ROCK HARBOUR.

There is a natural impression that all nstructional engineering work of the linary kind in Great Britain was sus- ided during the war, but in point of t it was found possible to keep quite number of schemes going in spite of concentration of effort upon definite r work. A case in point is supplied an extensive harbour improvement ich was begun in Great Britain a nth or two before the war. The heme included a new basin with an a of 2¼ acres and 1,500 feet of new ays. All through the war the work ceeded steadily, if slowly. Its most narkable feature was that the basin s cut out of solid rock to give an rage depth of 13 feet. The material avated was ingeniously used to re- im from the sea a considerable tract se to the harbour.

GRINDING ATTACHMENT.

The Hjorth Lathe & Tool Co., Boston, ss., have placed on the market an ernal grinding attachment that can used on practically any of the plain universal grinding machines now on market. The attachment is driven m a ceiling countershaft, and the ndles are of two types—one for deep d large holes, and one with tapered ors for small holes; the latter ac- mmodates small emery wheels and mond grinding plugs.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

FITTING TO THE BONE.

Do you want a good shoe fit? Then use the X-ray as they are doing in Great Britain in some stores. A simple self-contained X-ray apparatus has been produced by which the customer and the shop assistant can see, on a fluorescent screen, the bones of the foot. The picture thus given shows exactly the real structure of the foot, from which an intelligent shop man can gauge the type of shoe which will give the customer the support and comfort he, or she, desires. The elecric power required is so small and the exposure of such brief duration that there is absolutely no fear of any burning or ill effects from the use of this appliance.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force cannot replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments of machinery equipment.

Crankshaft Grinding Made Easy for the Repair Man

Here is the new Norton Autopart Regrinding Machine—designed exclusively for the automobile repair or regrinding shop.

It will perform every cylindrical grinding operation necessary to put an automobile engine in first class condition. It will grind pistons, piston pins, valves and *ALL TYPES OF CRANKSHAFTS.*

An engine is not properly repaired unless the crankshaft is reground. Car owners are fast waking up to this fact.

This machine has both the capacity and rigidity for grinding crankshafts combined with speed range and ease of set-up for handling every small cylindrical job of the repair shop.

It has made the problem of the automobile repair shop man a simple one—it will do *ALL* his cylindrical grinding.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

3 FOR 1

Indianapolis, Ind.

The **6" blast gate** furnished by you has proven entirely satisfactory.
It is **answering the purpose of an 8" gate valve,** which would **cost several times as much as a blast gate.**

THE BAUR CARBONIC COMPANY
(Signed) Oscar Baur, Pres.

'NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting.

You have the same opportunity to save practically two-thirds of what you now pay for gate valves.

Low in first cost and upkeep, easily and quickly operated, affording the full area of the pipe—these and other advantages make our New Air-Tight Blast Gate an ideal substitute for heavy, cumbersome, expensive and slow-acting gate valves.

This new Air-Tight Blast Gate is made in sizes from 2" to 16" threaded and flanged. Descriptive circular 210-T gives detail dimensions of all sizes. Write for copy to Canadian branch.

W. S. ROCKWELL COMPANY
Furnace Engineers and Contractors
50 CHURCH ST. (Hudson Terminal Building), NEW YORK

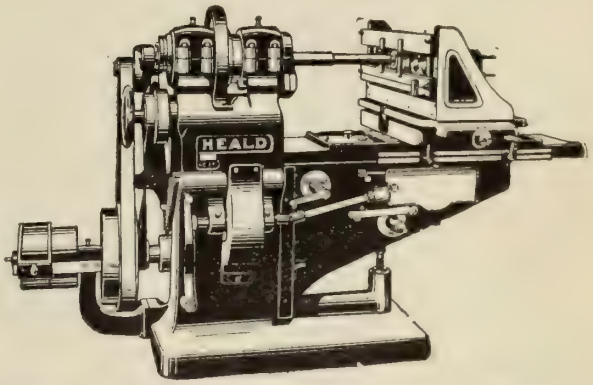
H.W. PETRIE LIMITED

CANADA'S DEPENDABLE MACHINERY AND SUPPLY HOUSE

The "PETRIE" policy represents the standard in high-grade tools and efficiency in service.

MACHINERY and SUPPLIES



REMEMBER the house of H. W. Petrie, Limited, when in need of anything in the shape of machinery and supplies. A colossal stock of machine tools of every description always on hand from which you are assured of getting the exact tool to suit your requirements. Included in this great array are many used tools. They are in good conditions and warranted to give satisfactory service. If you are seeking an opportunity to buy equipment at rock-bottom price don't fail to see our line of used machines.

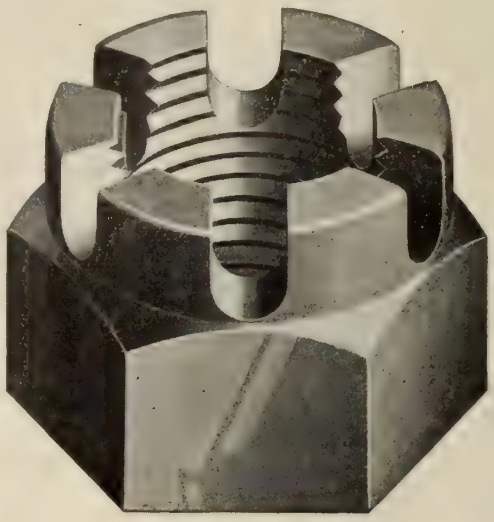
SERVICE.—A competent staff of engineers is at your service at all times; submit your problems to them; their advice costs you nothing and it is highly authoritative.

Another factor of importance to remember in dealing with the house of H. W. Petrie, Limited, is this: the quickest of service is always rendered on orders large or small.

Get the Cream of a Profitable Business

Regrinding Cylinders makes used motors better than New

Style No. 55 handles all sizes and shapes of cylinders



There is no business to-day that has the possibilities and which fits as nicely into a small machine shop, automobile repair shop or a concern doing welding, as the regrinding of worn or scored cylinders. Heald style No. 55 is built expressly for regrinding work. It is simple, moderately priced, self-contained, and has a very large capacity and range, easily taking care of singles, doubles, four and six en bloc cylinders.

You can't help noticing the good qualities of

Pratt & Whitney Taps

Their free cutting qualities, their extreme accuracy and their extraordinary ability to outlive others distinguish them.

The con-eccentric relief—a distinctive P & W feature—is the secret of their goodness. One-third of the cutting edge is concentric. The remaining two-thirds has eccentric relief. Taps can be sharpened at the only correct point—on the face of the cutting edge. Sharpening in no way effects their size.

Yes, they cost a little more than some others, but they're well worth the difference. Carried in stock as are all other P & W Small Tools at our sales offices and agencies as listed.

Three Good Thoughts—

Here are three good thoughts for mechanics to remember:

1. Have your set of Starrett Tools *complete.* Be ready with the right tool for any job. Don't borrow. Have your own tools.
2. Know your Starrett Tools. Study them. Be posted on every way to use them, so as to make your work easy to do—and be done well.
3. Don't let your Starrett Tools fall, or be knocked around. And don't let them get gummed up with dirt and grit. Be careful of them yourself and don't lend them to others.

When you buy precision tools be sure to say "Starrett."

Write for Starrett Catalog No. 22 and keep it handy.

DODGE

Couplings for lineshaft service everywhere

One style of shaft coupling cannot fill all requirements everywhere; conditions and individual opinions are too widely varied.

If you are prejudiced in favor of any one type of coupling, Dodge will provide you with the best coupling made in that type.

If you desire the opinion of Dodge engineers as to the proper type or types of couplings to use on any job, it will be gladly given, will be absolutely unbiased and will provide for operating economy in every way possible.

But whether you buy couplings on a preference basis or select them at our suggestion, be sure that they bear the name "Dodge." Only in this way are you certain of having the best.

THE JOHNSON FRICTION CLUTCH

The Case Against the Countershaft

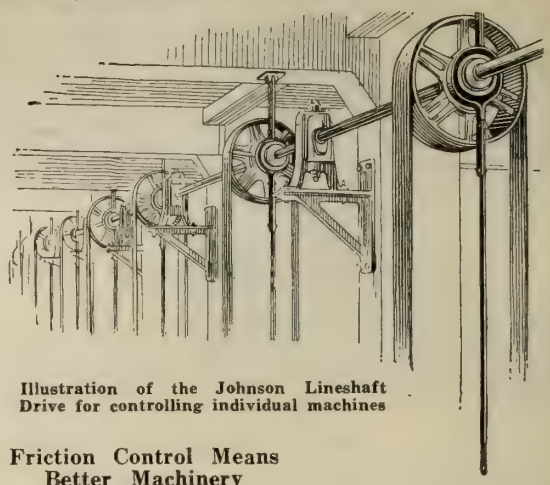
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.



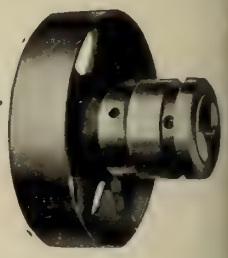


Illustration of the Johnson Lineshaft Drive for controlling individual machines

Friction Control Means Better Machinery

Whether it is applied overhead or in the machine itself.

Write for our Booklet "Clutches as Applied to Machine Building" and our Yellow Catalog.

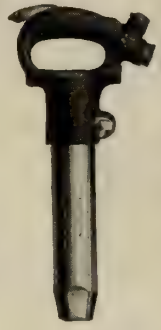
Cleveland Sand Rammers

FOR FLOOR, BENCH, PEIN AND FLASK RAMMING

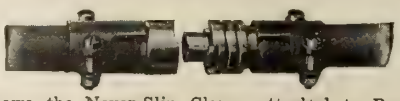
Cleveland Sand Rammers are made in several sizes and weights, and are adapted for all kinds of Foundry Ramming.



The Piston Rods are packed with a resilient packing which prevents any dirt from entering piston chamber and working parts—They are fitted with either Round or Flat Rod as required. Cleveland Rammers are light in weight, have high speed and practically no vibration, making them ideal foundry tools.

CLEVELAND CHIPPING HAMMERS

For Foundry Work. Are furnished in any required size or weight for grey iron or steel castings; they have high speed, and are adapted for fast chipping now required by piece-workers.



CLECO PRESSURE-SEATED AIR VALVES AND BOWES AIR HOSE COUPLINGS

Are Standard Equipment Everywhere

Both Valves and Couplings are pressure tight.

Bowes Couplings are instantly connected or disconnected.

Bowes Couplings are absolutely air tight under all pressures.

Above cut shows the Never-Slip Clamp attached to Bowes Coupling.

IN STOCK:—RIVETING HAMMERS, DRILLS, REAMING, TAPPING AND FLUE-ROLLING MACHINES, CORNER DRILLS, PORTABLE AND BENCH GRINDERS, PRESSURE-SEATED AIR VALVES, ETC.

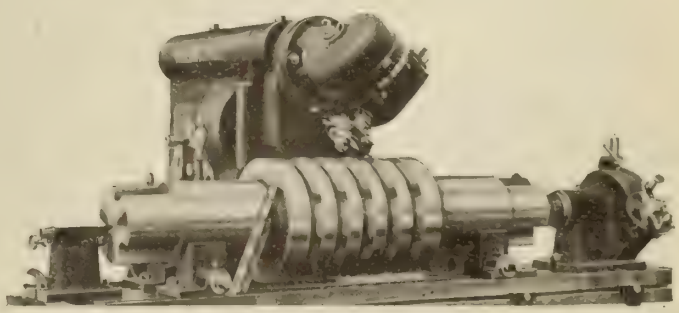
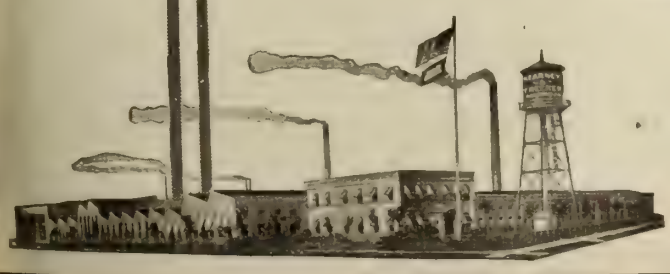
MILWAUKEE MILLING MACHINES



Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

Exhaust Systems

THE importance of the immediate removal of sawdust, shavings, abrasive dust, leather dust, etc., from machines cannot be over emphasized.

Better work, increased production, healthier and more contented employees are natural results when factories are equipped with well designed, thoroughly efficient Exhaust Systems.

Reed's "Shur-Pull" Exhaust Systems

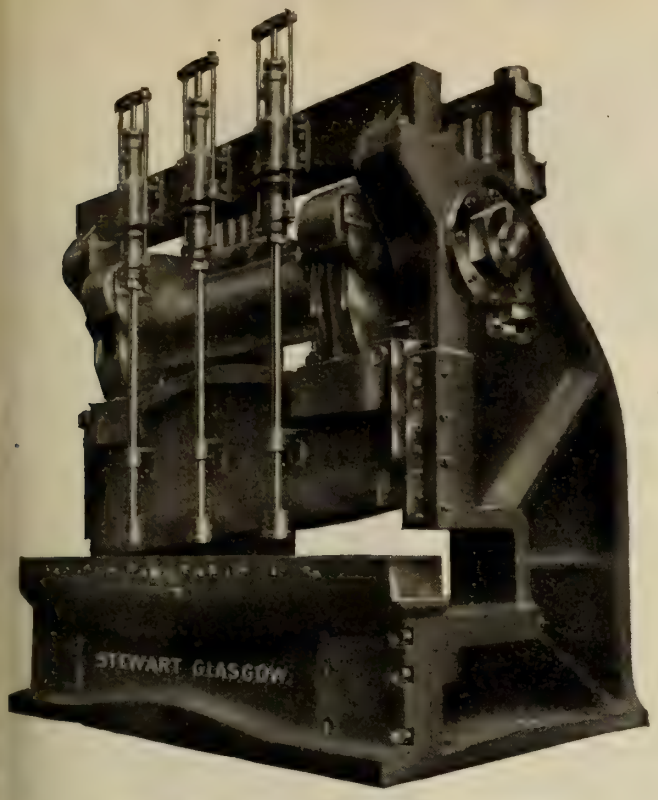
have stood the test of time

Each system is specially designed to meet the requirements of the work. No hit-or-miss methods are employed.

If you are doing, or contemplating, exhaust work, Reed Engineers will gladly collaborate with you.

"Shur-Pull" Exhaust Systems are Canadian through and through.

Tell us your exhaust problems and we will solve them



GEO. W. REED & CO., LIMITED - MONTREAL

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force cannot replace this service at an equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistant advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments of machinery equipment.

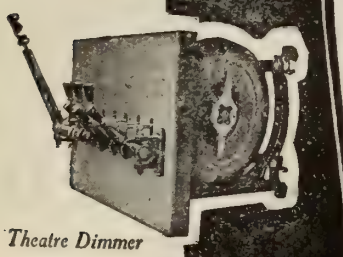
CUTLER-HAMMER

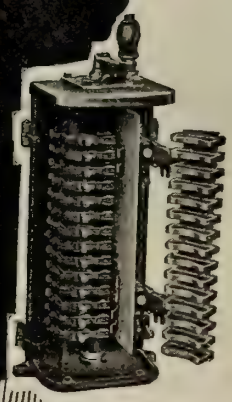
Automatic Starter

Lifting Magnet



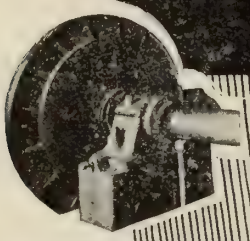
Compensator

Magnet and Control Devices



¶ Cutler-Hammer Lifting Magnets and Magnetic Separators have proved of exceptional value in the mining field, in steel mills and in many other industries for lifting and separating metals. The Magnetic Clutch and electrically operated Brake, used primarily in steel and rubber mills and for crane control repectively, are widely applicable to many industries where the gradual engagement or adequate braking of a load is desirable.

¶ In electric controlling devices of all kinds Cutler-Hammer is the recognized standard of dependability, whether for fine speed adjustment of a machine, extremely close voltage regulation, the wonderful light dimming and colour effects in a modern theatre, or the automatic control of heavy loads or other special operations.



¶ Details and recommendations of suitable Cutler-Hammer apparatus for your control problems are available at our branches.

Landis Threading Machines

Standard Labor-Saving Equipment

Landis Bolt and Pipe Threading Machines do better work in less time because of the distinctive design of the Landis Chaser, which operates in the same manner as a lathe tool. Placed at a tangent to the work it allows the machine to operate at a higher speed than is possible when a hobbed type of die if used:

The diagram illustrates the main characteristics of the Landis Chaser as compared with the hobbed type die. It shows the long life of the Landis Chaser, and the fact that both right and left hand threads can be cut with the same set.

These are some of the special features that will help you lower the cost of production. Landis Thread-Cutting Machines are considered standard equipment by leading manufacturers, whose hardest jobs they handle with complete satisfaction.

We are the Canadian Representatives and our nearest Branch will gladly send detailed information.

The Machining Of Spindle For High Duty Lathe

Efficient Lathe Practice—Examples Given Do Not Call For Elaborate Fixtures—Making a Cone Pulley Bush—Machining Head Gear—Work On The Lathe Spindle—Producing a Pulley Hub.

by J. H. MOORE

THE subject of efficient lathe practice will always be one of decided interest. The examples of work scribed in the following article do not all for elaborate tool holding fixtures, are typical of the average machine throughout the country.

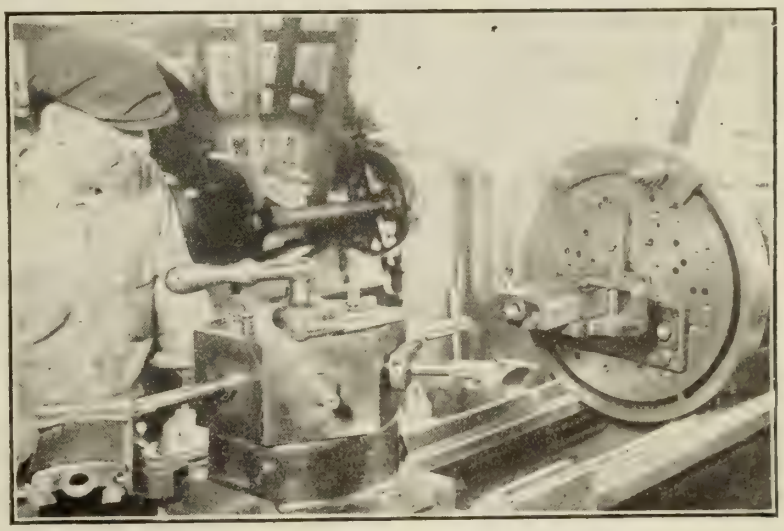
ake for example Fig. 1. Here we the top slide for an 18-inch high lathe. A special holding fixture sed as shown in the photograph, 7, and in this operation the slide ced, bored, and tapped in the en- lathe.

llowing are the steps taken. The le is placed in the fixture, which hly takes 2 minutes; it is drilled a one-inch drill at 205 r.p.m. in ap- mately one minute, after which it ced with a high speed cutter also ing at 205 r.p.m. The slide is now bored to 1.045 in., then the hole ghtly chambered with a tool in the s shown at position 4 in Fig. 2.

xt comes reaming, see position 5 g. 2. The hole is reamed to 1.055 with a solid reamer at a speed of r.p.m., this taking approximately conds. At position 6, see Fig. 2. ole is tapped, and at position 7, ole is finish tapped. The remain- ime is occupied in removing the work from the fixture, the floor to floor time on the slide being 9 minutes, 30 seconds.

Cone Pulley Bush.

The bush shown at Fig. 3 is used on the cone pulley of a 15-in. plain crank shaper and it is made from bronze. The operations are boring and reaming and an air chuck is used in holding the work. The chucking takes roughly 10 seconds, while the boring, which is done with a double end tool at a speed of 135 r.p.m., occupies 2 min., 10 sec. Reaming is accomplished with a 2 7/8-in. adjustable reamer, and 45 seconds is used up in this step. The removing of the part takes another 5 seconds, so that the complete bush is produced in a floor to floor time of 3 min., 10 sec.



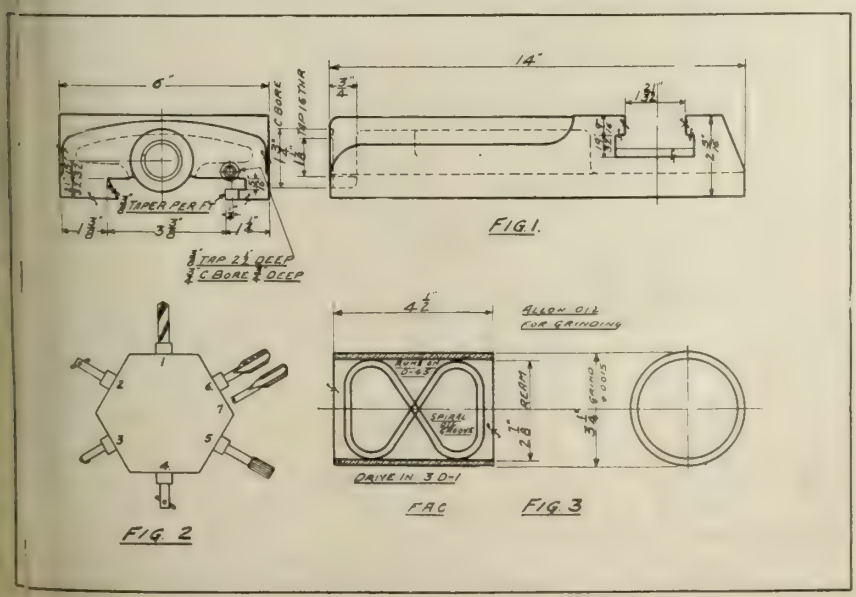


FIG. 7—SPECIAL HOLDING FIXTURE USED FOR FACING AND BORING SLIDE.

Illustrations by courtesy American Tool Works Co. Cincinnati, Ohio.

FIGS. 1 TO 3.—TEXT MATTER EXPLAINS THE VARIOUS PIECES.

Head Gear.

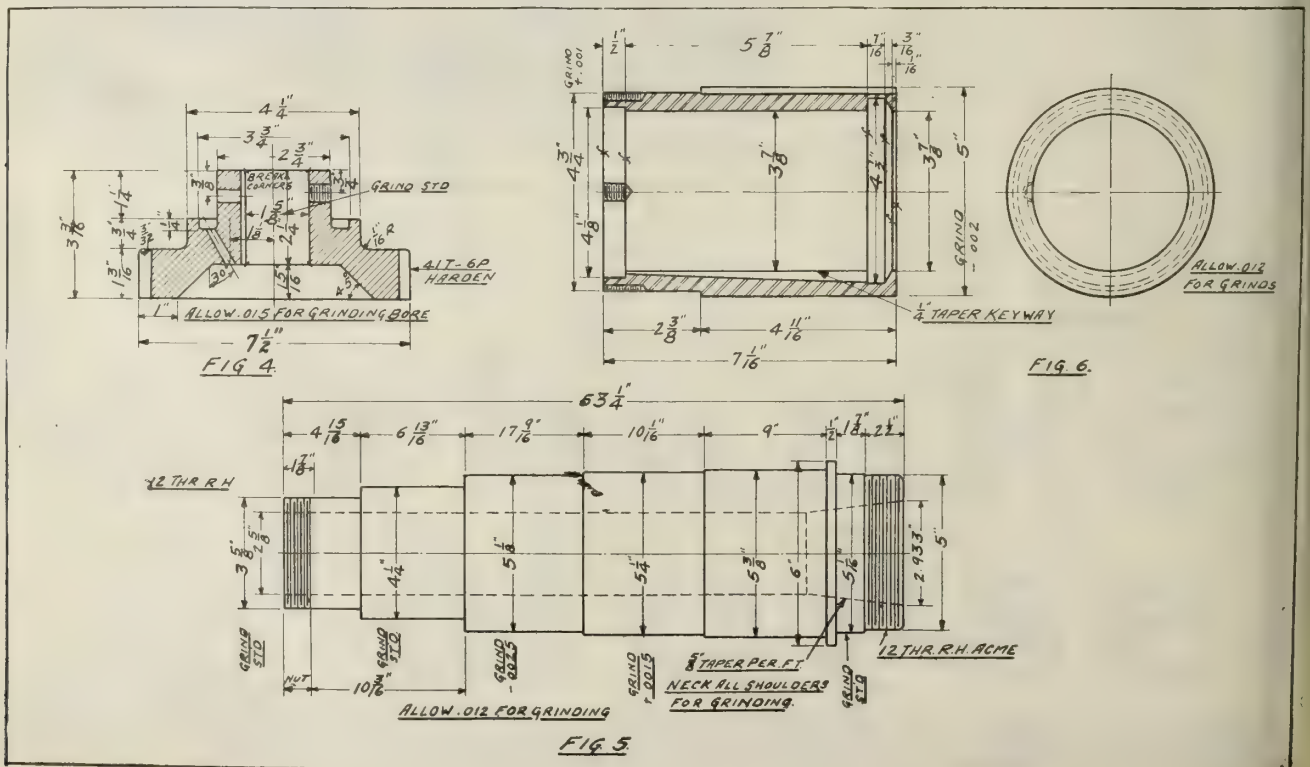
The next example, Fig. 4, shows a head gear made from an alloy forging which is completed in a floor to floor time of 57.7 minutes. Two settings are necessary, and in the first setting here is the procedure. The piece is chucked in a four jam chuck, and the top is rough turned. Next the large diameter is faced, after which the first cut on the hub is taken. The gear is now turned to 4 5/8 in. diameter, then the hub receives its second cut. The end of the hub is next faced; the oil groove is cut, after which the work is removed. This completes the first operation in a floor to floor time of 27.5 minutes.

The second setting calls for the work to be chucked as usual; then the top is turned; next faced; then bored about 3 1/4 in. diameter for 1 5/16 in. deep.

SHOWING OPERATION ON THE HEAD GEAR.

FIG. 9—SHOWING OPERATOR WORK ON SPINDLE FOR 30 INCH HIGH DUTY LATHE.

The bevel comes next in order, this completing the second setting in 30.2 minutes, or a total time on both set ups of 57.7 minutes. Fig. 8 shows the lathe in actual operation on this part.



Work on Spindle.

The spindle shown at Fig. 5 is used on a 30-inch high duty lathe, and Fig. 9 depicts the operator at work on one of these spindles. Following are the steps taken in its completion. The spindle is placed in a special fixture, then the 6-in. diameter is faced in two cuts. The end of the spindle is next faced, then the 5-inch diameter portion is rough turned. The 5 1/16 in. diameter is next to be rough turned, after which the 6-in. portion is finish faced. The end is now finish faced, and the 5 in. part finish turned. The corners are next broken, these steps complete taking 53 minutes.

The shaft is now drilled for chasing, after which an Acme R. H. thread of 2 per inch is completed on the 5 in. diameter portion of the spindle. This operation takes 10 separate steps. After these steps have been completed the taper hole in the spindle is bored, also the center hole. From the start to the finish a total time of 479 minutes is necessary to complete the piece. It might be well to add that a limit o hours is allowed on the spindle though the time steps as mapped shows the floor to floor time to be minutes.

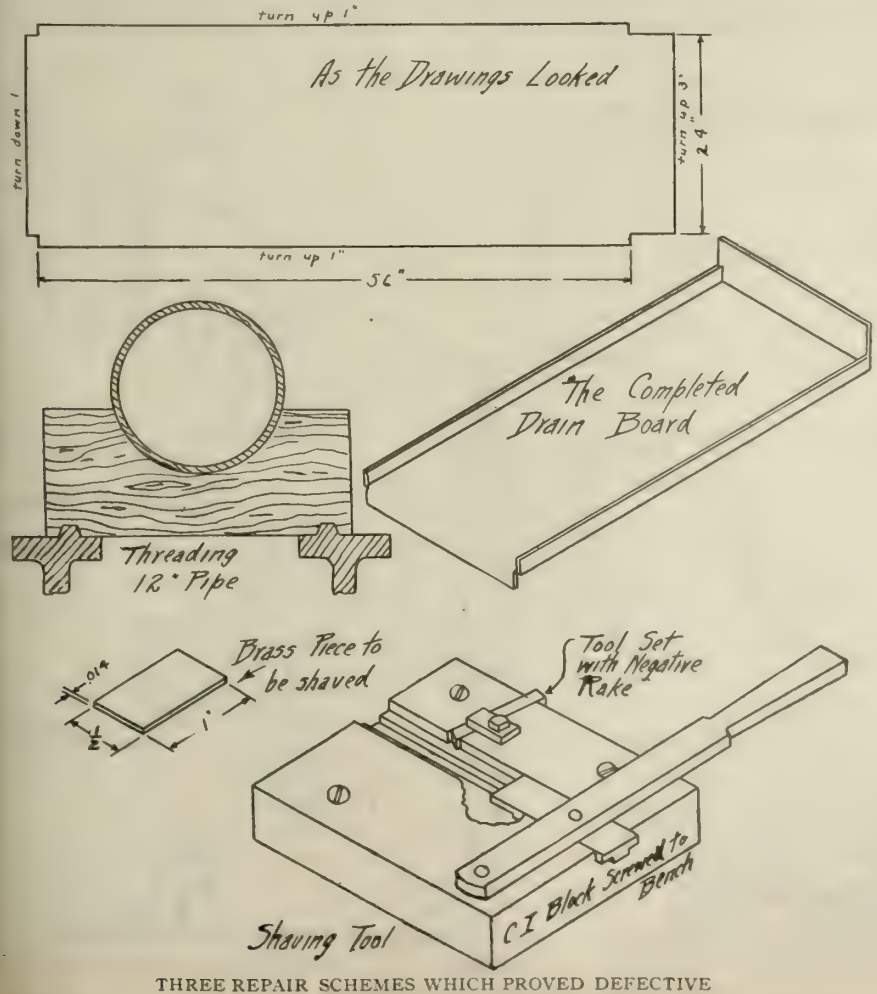
Pulley Hub.

The last example, Fig. 6, shows a ley hub made from machine steel w is finished in a floor to floor time c minutes. A three jawed univ chuck is used for holding the hub, the first step is to bore half way thr the piece with an inserted high s cutter. The part is now rechucked the remainder of the hole bored. next step is finish boring,a single high speed cutter being used.

FIGS. 4 TO 6—SHOWING THE HEAD GEAR, PULLEY HUB AND SPINDLE.

Outside Jobs And How They Were Accomplished

The Repair Business Is An Exceedingly Interesting One—How Channels Were Straightened—Turning Heavy Shaft On Its Own Bearings—Making a Rejected Job Pay, and Other Valuable Hints.



By DONALD A. HAMPSON.

THERE is always variety in the jobbing and repair business, even if there is not much profit. Some owners object to having their plants known as "job shops" or "repair shops," thinking that it casts a reflection on the place—one man went so far as to make his sign and his stationery read, "Research, Development, and Specialized Repairs," in the hope that it would lend dignity to his business. But after all, the biggest locomotive and shipbuilding plants take in repair work as a regular part of their business and a visit to a good many of the most highly specialized machine tool plants during slack times shows outside repair work and special jobs being done.

The repair business can be made to pay if each job is charged with all the incidentals belonging rightly to that job but when you "throw in" half an hour of a busy executive's time or don't charge for an hour's drafting or do a hurry job without adding enough to straighten up things the next morning, or fail to add for dressing a set of chisels that were ruined on some hard steel castings then you are going to lose money. Frequently a shop makes an estimate on a piece of work and fails to add the cost of estimating to the price or, in the struggle to get business, will not charge for some items such as when a boy tends the hack saws or runs a bolt cutter and he stays on that job whether the machines are running full time or not.

More extensive jobs ought to have a liberal charge added to the price to cover the work of "running down" various items of material and parts that have to be secured from a distance—no one would believe the amount of effort involved in such work until they have tried it once.

But though the business side may have its charms, it is the engineering features that appeal to the mechanical mind. The ingenuity that does the seemingly impossible or that disregards conventional methods and gets out the work with the equipment (or lack of it) at hand. This is the side of the jobbing business that appeals to the mechanic, it is part of a liberal education to work in a shop doing such work.

THREE REPAIR SCHEMES WHICH PROVED DEFECTIVE

How We Straightened Channels.

They were putting up the elevators in a new hotel down town and when they came to place the channels they found them badly bent, due to mishandling on the railroad. They were 12" channels and we had no special facilities for structural work, but we agreed to try to straighten them. We had a planer with 15 ft. table and the channels were only a little longer than this.

Actually, it was much easier than we had anticipated. The high part of each bend was chalked, then this was placed down and resting upon a one-inch parallel, and heavy straps bolted across the channel on either side at distances of about 15 inches. By drawing the straps down with the bolts, the channels were quickly straightened. The bends where the web was up were hardest to straighten and, to better stretch the metal, peening on top was resorted to along with pressure.

Turning a Heavy Shaft in Its Own Bearings.

The local brewery was extremely busy turning out "cereal beverages" and as we had done most of their work, we got the call when they wanted a section of the ice machine crankshaft turned. It seems that the flywheel had been loose for a good while, eating into the shaft and getting worn in the bore so that there was a continual pound. A new wheel had been ordered from Milwaukee and would be delivered the following Monday, but, in the meantime, the shaft must be dressed off straight and 1/16" smaller, which was the size the new wheel was to be.

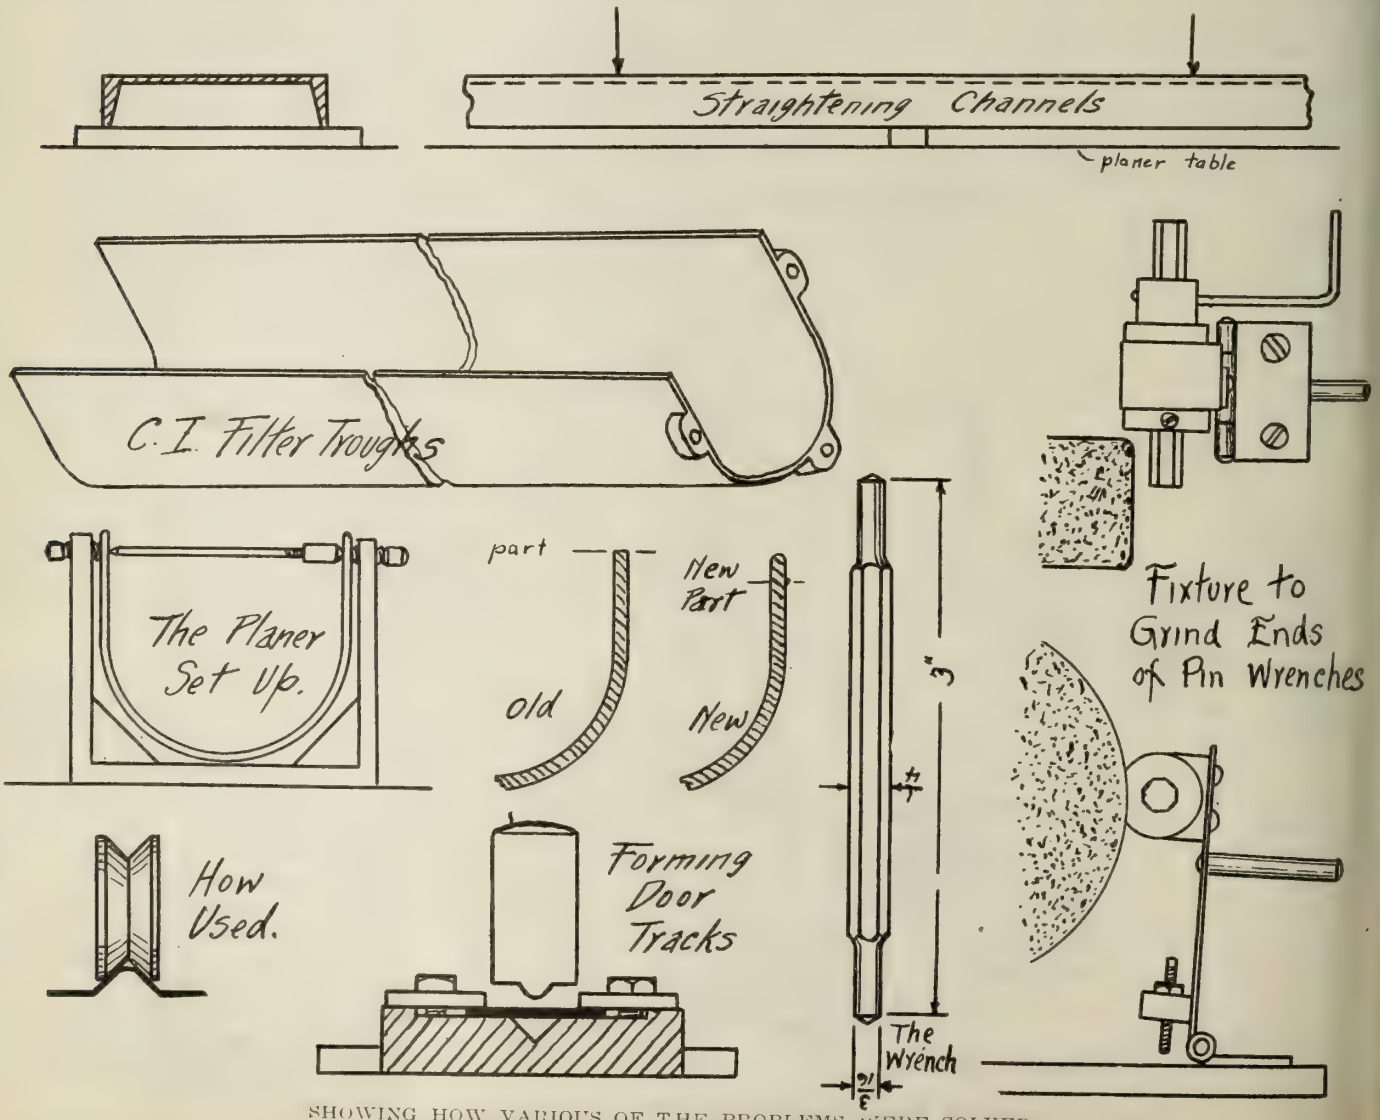
We looked the job over and decided that the best way was to use the cross rail from the 20" planer. Accordingly, a pair of brackets were cast and machined—these fitting the back of the cross rail, and the face of the ice machine pedestals. The clapper block of the tool head was bolted down. Three Armstrong tool holders—straight, R.H., and L.H.—were provided and one of the boys set out for the brewery. He was back before noon the next day, having set up his fixture and turned off a 15" section of 10" shaft. The engine throttle valve was the "gear box" that produced just the right cutting speed for the work.

Big Press Work Done With Hand Tools.

A certain rich man wanted to get brass tracks made for the sliding doors in his house to replace those of blue steel which were originally installed. The drawing shows the shape. If we had received an order for ten thousand feet, we would have rigged up some arrangement to roll the section, but only eight 60" lengths were wanted—and these regardless of cost.

Our tools consisted of a piece of cast iron and one of steel—and a planer. We made a rough pattern and got a casting five feet long that was bolted to the planer and cut with the proper shaped channel. The piece of steel was whittled to form the punch, or male member, and this was to be used with a hammer. Straps were put on each side of the casting to hold the brass light enough to permit drawing but firm enough to keep the flanges out flat and straight. By using a soft brass, the forming was easily done—the work was gradually formed, starting at one end and working over the whole length with the "first draw," then going over it a second and a third time, until when finished it looked very nearly as good as if formed in a big press or rolled.

A Small Tool Job.



Our shop did the screw machine work for a suburban plant without such facilities. One of their products was operated by a little pin wrench such as represented in the drawing. Originally, these were made of 3/16" C.D.S., pointed and cut off, but a better article was desired and they settled on octagon tool steel with each end turned to fit their holes.

This steel was secured from a house that supplies steel for dentists' tools—in fact, enough steel was robbed from a dental order to make 10,000 of the pin wrenches under consideration. Long ago we formed a high regard for the quality of the steel in these tools with which the dentist prys and probes and punches and so we doubted the practicability of running off the bars on the automatic, but the steel salesman assured us that the toughness of the tools we so respected came from the temper and that the steel he would send could be worked at automatic speeds.

Well, it could not—nor at any other speed. We tried all speeds and feeds and various cutting compounds and ultimately ruined a perfectly good set of tools. The experience proved that the steel, just as it was, would make ideal pin wrenches for our customer—tools that would neither bend nor break, so we designed a "fixture" to grind the octagon down to a round.

An eight inch T hinge formed the basis of the fixture. In use, the butt end of this was fastened to the table of an emery grinder with the strap end pointing upward and carrying the work holder. The latter consisted of a socket rivetted to the hinge and a piece turning in the socket whose axis was parallel to the grinder spindle. The piece that turned was collared to keep it in the same relation to the socket, one end carried a short crank, and the other end was drilled to receive the octagon stock.

The latter was sheared off to length. Then the pieces were placed in the hole and held by a set screw and the operator brought the work in contact with the emery wheel with his left hand while turning the crank with his right. In this way, the desired round was quickly produced. A stop was used to maintain the size within given limits. This method was not as quick as a screw machine process, had the latter been possible, but it did a good job at a reasonable

SHOWING HOW VARIOUS OF THE PROBLEMS WERE SOLVED.

price and with little tool expense; it used up material that otherwise would have to have gone through more or less negotiation and it saved the cost of heat treatment.

Turning a Rejected Job Into a Paying Contract.

A nearby foundry does the casting for a large filter manufacturing concern. Most of this work is installed without machine work other than some drilling but occasionally there are parts that require machining and the foundry gets bids from the various shops about town. One of these jobs was the work on 100 troughs about seven feet long and weighing 250 lbs. each (see sketch). The long edges were to be planed, holes drilled in each end, casting painted, and delivered on motor truck. Our bid was $4 each; a neighbor bid $2.50 each and got the job. Also, he lost money and when the job came up again he refused to do them at any price, so we got a chance at the $4 price—and made good.

To hold the work on the planer, conventional brackets were cast and set-screwed. These held the work steady, with a screw post inside at the three bracket positions to prevent collapsing. A clamp at the bottom of the U at each end was all the fastening required. A well planned handling arrangement simplified the on-and-off work.

The other people had lost out on the planing and the drilling. The narrow edges of the castings often showed hard spots, little chilled overflows, and sand. They could not use a flat tool and feed downward and the work sprung and jumped under cross cuts. These were the planer troubles we had anticipated and when we got the job we avoided them by changing the shape of the pattern. Instead of a flat edge coinciding with the parting line, we changed the edge to half round and arranged with the foundry to part the moulds about an inch back—the width of the planed edge made no difference to the filter people, who merely required a straight water level line.

The clean round edge made it possible for us to use a flat nosed tool and plane directly down. The tool was always cutting clean, soft metal, with the thrust in the direction of the casting's greatest stiffness. When set, the tool was good for 50 or more castings. We averaged three castings per hour.

After planing, the troughs were delivered on the floor ready for drilling. The end holes were the biggest job of drilling. We had a Stow electric drill, geared to 500 R.P.M., which was rigged up for this work. A plate was cast to clamp to the lugs on the ends and this plate had cast lugs, or cradles, to place the drill in for each of the three positions. Incidentally, the plate carried the drill bushings. A lever was provided and all the workmen had to do was to clamp on the plate, place the drill in a cradle (not even clamp it), slip in the lever, and push. We did well at the $4 rate, in fact, we would not have lost if we had received only $2.50. But the thing that saved us money was not machine shop practice at all—it was the slight change in the foundry work.

Another Use for Wood.

Some short lengths of 12" pipe had to be threaded for a steam plant. Nobody within a hundred miles had a pipe machine and we had no pipe centers for this size. And as we didn't want to go to the expense of making them up for one job we cut a piece of 2" maple as shown by the drawing. A light band over this was added for security, though the weight would almost had held the pipe down. One end chucked and the other in the wood steady rest made a good set-up—one that may be used for other extraordinary jobs.

Shrinking on Bands Without a Heater.

New wheel centers were being put under a fire truck. We got the job of putting the old felloe bands on the new wheels. These bands were 30" diameter and about 7" wide and had to be shrunk on. Lacking better facilities, we set each band in turn on four fire bricks out in the yard. The wheel centers were also taken out in the yard and placed nearby, ready to be fitted, and with three steel pieces clamped on to serve as stops to correctly position the felloe. A wood fire under the band quickly brought it to a red heat, two men with tongs picked it up and dropped it over the center to the stops—and went back to the next band.

Even Housework Has Its Roots in the Machine Shop.

A State institution near us was gradually installing metal drain boards in the numerous kitchens. That doesn't sound like machine shop work! These were made of ⅛" iron sheets with edges turned up and down, fitting into existing wall spaces. It had been the practice to buy the sheets locally, of a size near the requirements, and send them to a distant sheet metal shop. One of the managers wanted us to try the job—we told them we had no sheet metal machinery but we knew we could bend them if they didn't object to a few dents. And now we have four or six a year to get out.

Again the planer comes in handy for other work. We first cut a square notch out of each corner. The first bend was always an "up" bend the long way though. We made it by clamping to the planer table and hammering the sheet downwards against a vertical face; this was done on a wide planer with just the bend width overhanging the edge and with the opposite edge blocked so our hammering did not disturb the parallel setting. Then the piece was moved to a narrower planer where the bent edge could lap over and act as a stop while the second long side was bent.

After that the trouble began, though by always backing up the piece against the thrust of the blow we got along pretty well. We would select from the stock rack the longest piece of square or rectangular that would go between the turned up edges, place this near the edge of the planer with stops (posts) behind, and clamp the bent sheet down on top with 1" or 3" overhanging as the case might be; to clamp the job securely, we would use a bar of 2 x 3 laid clear across the top. The final bend on the end was always the opposite way and, as such, it came easily. With a little care, it was possible to turn up the edges, hammering them so that the joint was water tight.

Shaving Brass Slips.

In connection with a manufacturing job, we had several thousand pieces of brass as shown by the drawing that had to be re-sized from an average width of 0.500" to a close 0.499". We tried several methods of doing this, only to learn that there was no royal road to the end. We finally made the simple fixture shown and pushed the brasses through one by one. This sounds slow, but considering the accuracy we got and the fact that one of the girl helpers soon acquired speed, we got out of it quite nicely. Our cutter was a 5/16" square high speed bit and our fixture made of an odd piece of cast iron.

INTERESTING MAPS.

We have received two interesting maps from the Musson Book Co., Ltd., Toronto, dealing with Eastern and Western Ontario respectively. These maps are very well prepared and show not only the main roads, but every secondary, side, and concession road. Every railroad, city, town and village is also listed. These maps should appeal to business men generally, both for pleasure driving, or for use when planning motor truck hauls.

CARBON CONTENT.

The carbon content of gray cast iron affects the melting point, the higher the carbon the lower the melting point. The melting point of the oxide of cast iron is higher than that of the metal, which fact makes it necessary to use a flux to dissolve the oxide or cleanse the molten metal. Gray cast iron containing 6.0 carbon melts at about 1,920 degrees F.; 4.0 carbon at 2,100 degrees; and 2.5 at 2,192 degrees. The oxide fuses at about 2,450 degrees.

Is It Possible To Minimize Drawing Office Errors?

There Are Certain Common Errors That Crop Up In Most Drawing Offices—A Proper System Of Checking Should Be Used Whenever Possible The Design and Detailer Should Hold Consultations.

"I WAS once told in all seriousness that draftsmen employed in a certain establishment did NOT make mistakes. If a mistake was made, the delinquent was not given a chance to repeat the offence, being dismissed forthwith, and his place filled by a less fallible individual." So comments W. E. B. B. in "Mechanical World." He continues:—

On reflection, one is obliged to conclude that the survivors at that particular establishment must have been veritable supermen, and doubtless by now have all obtained responsible and lucrative Government appointments. While it is easy to see the absurdity of such bombastic exaggeration, it is certainly possible by adopting proper methods to avoid many of the vexations and delays caused by mistakes in drawings.

Mistakes most frequently met with are:

(a) Arithmetical blunders, causing fouls, etc.

(b) Errors of judgment, resulting in failure of the structure or machine to do the work for which it was designed.

(c) Faulty design of castings, forgings, etc., due to imperfect knowledge of the processes of manufacture or of the limitation imposed by shop equipment.

(d) Mistakes resulting in great difficulty or impossibility of assembly of machine components.

The arithmetical blunder can and should be almost eliminated. The surest way to effect this is to have every drawing checked by an independent authority before it is issued to the works. In the small office this may best be effected by an exchange of work between the draughtsmen themselves.

A Checker Essential.

In larger concerns it will pay to employ a checker exclusively for this work. This plan has a good deal to recommend it. Checking calls for rather special qualities of mind, and it is possible for a man to be a fully competent draughtsman yet a very indifferent checker. It may, of course, be argued that all this takes valuable time and adds to the drawing-office charges. It must be remembered, however, that time spent in this department may be saved many times over in the shops, besides the probable saving of many costly components from the scrap-heap.

Errors due to (b) are best eliminated by thorough and conscientious work in the designing and estimating office. If due care and forethought are exercised here, the work of detailing is rendered vastly easier and some assurance given that the preliminary ground has been well covered and working contingencies foreseen.

It is an excellent plan, wherever possible, to bring designer and detailer together for a consultation before proceeding with a job.

All possibility of misunderstanding is thereby eliminated, and the specification may be discussed in detail. Mistakes have occurred through lack of this precaution, and the draughtsman has been led unwittingly into a trap through some ambiguity in the design.

As in other departments of engineering concerns, the closer the co-operation betwen designer and detailer, the smoother will be the progress of the work, and chances of error coming under this heading will be reduced to a minimum.

The best guarantee of immunity from errors due to (c) is provided when the works management are taken into frequent consultation.

COMMON MISTAKES. HOW TO AVOID THEM.

Arithmetical blunders. Errors of judgment, resulting in failure of the structure or machine to do the work for which it was designed.

Faulty design of castings, forgings, etc. Mistakes resulting in difficult, or almost impossible, assembly of machine components.

To avoid errors, it is an excellent plan, whenever possible, to bring designer and detailer together for a consultation before proceeding with a job.

When Doubt Exists.

Wherever doubt exists as to the relative merits of castings versus forgings, or how best to dispose ribs to permit of ease in moulding, whether it is more economical to make a new pattern or to alter an existing one—these are points best referred to the practical man whose experience in such cases is of the utmost value.

For similar reasons the machine-shop foremen should be consulted. It sometimes happens that the machining on a casting may be done in half the time merely by the addition of an inconspicuous boss or lug or by a trifling rearrangement of the piece.

Information with regard to the maximum capacities of various machines, size of largest lathe gap, greatest stroke of planing machines, a list of cutters for spur-gears and of hobs for worm-gears, with any tooth numbers that should be avoided—all this kind of information is of frequent value to the draughtsman, and should be filed for reference in a convenient form.

Much may be learnt from an occasional visit to the shops while work is in progress, and most firms give every facility and encouragement to the draughtsmen to keep in touch with the practical aspect of their work in this way. When engaging the drawing-office staff it is usual to give preference to those candidates whose qualifications include some years of practical training in the shops.

The value of such training is obvious, not only in imparting a knowledge of shop processes, but in implanting a realization of the difficulties with which the shops have to contend, difficulties which are quickly grasped when the draughtsman himself has had first-hand experience of them. There is also a moral value in some years of shop training which is undeniable. Its effect on character and the broader outlook it conveys by reason of direct contact with the concrete elements of the profession and with those whose business it is to "deliver the goods," engenders a lasting realization of the necessity for co-operation between drawing-office and works which is of the greatest value.

Class (d) represents pitfalls which can be avoided only by adequate supervision, the exercise of imagination and watchfulness on the part of the draughtsman at every stage.

An excellent practice followed by many large concerns is to file a record of the behaviour of every machine under test prior to its despatch to the customer. In this way the designer is able, by reference to the record for machines of a similar type to the one he is dealing with, to avoid many pitfalls and so profit by the accumulated experience of the past.

It is not uncommon for mistakes to occur through lack of uniformity in the method of projecting views on drawings.

It matters little whether the "first angle of projection" method or the "third angle of projection" is adopted; but what does matter is that one system is adopted and is rigidly adhered to, otherwise there will be confusion, and sooner or later serious mistakes will be made.

There is no uniformity at present in drawing-offices regarding this question of projection, and should a man move from one firm to another it is quite likely that he may have to change his method of projection, and for a while at least he will be in some danger of falling into his former habit of regarding the different views. It seems a pity that this matter cannot be thrashed out and a standard system of projection adopted universally for engineering work. In conclusion, it may be worth while to point out for the benefit of those who have a bias towards "hustling" methods in the drawing-office, that the quantity of paper which a man covers is of secondary importance to the amount of care, deliberation, and forethought which is embodied in his work. There are doubtless men whose best work is done in a hurry, but they are the exception rather than the rule, and usually their efforts are spasmodic and their accuracy too often in inverse ratio to their speed.

The ultimate aim of the management should be to strike a just balance between rapidity and exactitude.

ALIGNING REAMER.

The Chadwick and Trefethen, Portsmouth, N.H., have brought out a new type of aligning reamer. In this new tool they embrace the general principle of their six blade adjustable reamer, with an adjustable bushing that forms a pilot for aligning. The back parts of the blade are ground cylindrical, also forming an adjustable guide after the cutting blade has passed through the first hole, retaining the reamer in line for the second hole. Cutting parts are made of special alloy semi-high speed steel. This design is adaptable to the reaming of automobile piston pins and work of similar character.

WELDING AND CUTTING

Oxy-Acetylene Welding Cast And Sheet Aluminum

Malleable Iron Also Included—Cast Aluminum—Preparation of Part—Preheating—Question of Flux—Puddling and True Method of Welding—Treatment After Welding—Similar Data on Sheet Aluminum.

In the March 24th issue of Canadian Machinery, we published, in our welding section, information on the welding of iron and steel. In the present material we will follow up the subject of oxy-acetylene welding and cutting considering the welding and cutting of malleable iron, cast aluminum, and sheet aluminum.

Malleable cast iron is probably more difficult to handle properly than any other metal. Castings to be made malleable are made of white iron where the carbon is in the combined state (not in the free graphite form, as in grey iron). During the process of making the casting malleable, some carbon is removed. The rest goes out of combination and remains in the iron where it remains free, not in the graphite form, but as true carbon. With the carbon in this form, the casting is soft and ductile like wrought iron. If a malleable casting is heated, as in welding, the carbon at once enters into combination with the iron and makes it hard, brittle and no longer malleable.

It is best to consider the welding of malleable castings from the viewpoints of two users of the welding process:

1st The manufacturers of malleable castings.

2nd The repair man.

When castings have to be repaired by the manufacturer, as they come out of the sand and before they are treated to make them malleable, prepare and weld exactly the same as cast iron. Use cast iron flux. Use a white iron welding rod. On no account use a filler containing silicon—iron containing silicon cannot be made malleable.

Castings that have been made malleable will lose their characteristic quality if welded and it is necessary that after welding, as described above, they be treated by the manufacturer. In the case of malleable parts broken in service and where the repair has to be made by the owner or a repair man, prepare as for cast iron, but as a welding rod use Tobin bronze with a brass or bronze flux. This will give an exceptionally strong joint, but one which of course can be detected by its appearance. Care must be taken to not bring the edges of the casting to a higher temperature than is necessary to make the Tobin bronze adhere satisfactorily. If this precaution is not observed the malleable properties will be destroyed.

Cast Aluminum.

The welding of aluminum castings at first offers some difficulties to the operator and experience with this metal is required before thoroughly satisfactory results will be obtained. The difficulties that arise are due to the fact that aluminum has a comparatively low melting point (1,200 deg. fahr.), whereas the conductivity and specific heat of the metal are high. Due to this fact, a comparatively large welding flame has to be employed on the work, thus calling for skillful manipulation of the blow pipe to prevent holes being burned in the parts operated upon. Aluminum in its pure form is seldom used for castings which are, as a rule, alloys of aluminum and copper, or aluminum and zinc. The aluminum-copper alloy is much easier to weld than the aluminum-zinc alloy, due to the facts that there is less tendency to crack on cooling and that oxidation is not so rapid.

To insure good work with aluminum it is essential that the work be absolutely clean. Most aluminum castings that have to be repaired have generally been in contact with oil or grease. To remove all traces of oil from the aluminum takes some considerable time, as the oil seems to penetrate into the metal. It is best to heat the castings slowly over a mild charcoal fire and carefully wipe away the oil as it "sweats" from the metal. In some cases gasoline can be used for cleaning aluminum or other castings to advantage.

Parts over ¼ inch thick must be bevelled the same as in the case of cast iron. Very careful setting up and aligning of the parts is necessary. As aluminum castings approach their melting point, the metal becomes very fragile and unless careful precautions are taken, the castings are apt to collapse or become distorted during the welding.

In order to prevent collapse during the welding and preheating operations, it is good practice to place a sheet of paper on the inside of the casting next to the crack to be welded. Back this paper with damp fire clay and pack up with asbestos fibre until a firm support is obtained. The paper prevents the fireclay from getting into the weld. With this light backing, or mould, the castings can be welded easily. The mould should be large enough to cover sufficient area around the crack so that the heated aluminum in the vicinity of the weld will not break down. Whenever a weld is to be made close to a bearing, it is necessary to remove the babbitt (which would melt) and then clamp mandrels in the bearings to keep them in alignment.

Preheating.

The beginner should preheat the casting except in cases where the part to be welded is a projecting lug or flange. After the welds are made, except in the case of a lug or flange, the work should be gently, uniformly reheated and cooled slowly, thus insuring the removal of any internal strains. Preheating or reheating when done must be carried on carefully and slowly. The casting should not be preheated to more than 900 deg. fahr. Above this temperature the metal gets very fragile and is apt to collapse. It is generally best to preheat aluminum work with an illuminating gas torch, using very little or no air, so as to give a large bushy flame and avoid localized heating. The torch, however, must not be left playing on one part of the casting too long. It should be controlled by a workman, who should keep the flame moving constantly. When preheating aluminum castings, it is advisable to test the heat of the metal with a stick of half and half

solder. As soon as this will melt, on touching the casting, it shows that the work is heated sufficiently, and is ready for welding.

For a filling material when welding aluminum castings, a rod preferably of the same thickness as the mteal to be welded should be used. Alloy aluminum rods should be employed.

Opinions vary as to the necessity or desirability of employing a flux when welding aluminum castings. A good deal depends on the method employed in making the repair—that is, whether the operator employs puddling or true welding. Remember that oxide of aluminum is very easily formed; it is heavier than the metal and consequently tends to sink into the body of the molten mass from the surface, where it is formed. The melting point of the oxide is much higher than the melting point of the metal. The presence of oxide in a finished weld will render it brittle and spongy. It is therefore essential that it be removed either mechanically, as is claimed can be done when puddling is employed, or by means of a flux. The flux must not only act on the oxide on the surface, but throughout the molten mass as well. The flux, when used, must be of good, proved quality and should contain no acid or alkali which might have an injurious effect on the weld if traces happened to be left in the body of the weld. Do not let low prices guide you in the selection of a flux. The ingredients in a good flux are costly.

The flux should be applied with a heated welding rod, as in the case of cast iron, and should be used sparingly. Aluminum flux should at all times be kept in air-tight cans as it quickly deteriorates. Repairs to aluminum castings by the oxy-acetylene process can be performed in two ways—the puddling method and true welding method.

The Puddling Method.

The operator must provide himself with a ¼ inch or ⅜ inch steel rod about 18 inches long, flattened at one end. The welding flame should be carefully regulated. A slight excess of acetylene is desirable and tends to prevent oxidation. Do not touch the work with the white cone of the welding flame. Play the blowpipe flame on the line of weld and bring it to a molten state, then scrape the surface with the flat end of the iron rod or paddle and remove traces of dirt and oxide; reapply the blow pipe flame and add welding rod, after a little rod is added lay aside the rod and take up the paddle, which should be kept hot at the flat end. Keep on playing the blowpipe flame gently over the added metal and skim the oxide formation from the surface with the steel rod. Then scrape the bottom of the joint through the molten metal and bring any dirt or oxide to the surface and skim off. Then add more metal and repeat the puddling until the repair is effected. Welds made by this process, although reasonably strong, are apt to be somewhat porous and are not as sound as welds made by the true welding method next described.

True Welding Method.

Regulate the blowpipe flame as in the puddling method. Play the flame along the line of weld and bring a short length of the line to a molten state. It is difficult for the beginner to judge when this is accomplished and at the start it is best to keep gently touching the work with the welding rod to find out. While melting the casting along the line of weld, warm up the end of the welding rod in the blue part of the flame which is not actually playing in the crack. Dip the rod in the flux powder, some of which will adhere to the rod. Then start and melt some of the rod into the weld, stir the molten metal with the welding rod and get it to flow uniformly. If uniform flow cannot be obtained add more flux. Repeat until the repair is completed.

Treatment After Welding.

Reheat when necessary. The work must be allowed to cool very slowly and should be protected from air draughts. Wash off with warm water any traces of flux. A welded joint is easy to finish. Experience shows that a Vixen file or wood rasp is preferable to the ordinary file for this work. Do not use any of the so-called aluminum solders as a filler when welding aluminum. Solder should be used only to build up worn surfaces, or to repair cracks in parts of castings which are not under strain and strength is not essential.

Sheet Aluminum.

Sheet aluminum is as a rule pure metal and has to be handled somewhat differently from an alloy. Where welding has to be done, the sheets are very rarely over ⅛ inch in thickness. If they are, they can be welded in the same way as a casting, except that drawn aluminum rod must be used as a filler and sheet aluminum flux used. Preheating is seldom necessary and any reheating or annealing that may be deemed advisable along the line of weld can be done with the blowpipe flame, using a slight excess of acetylene. Bevelling of the plates before welding has hardly ever to be done and practice will show that the plates tend to bevel themselves as they come up to the melting points. along the line of weld.

The welding of aluminum sheets less than ⅛ inch in thickness will be found to be a somewhat delicate operation and a good deal of practice is required before sound, neat joints can be made. The process is somewhat similar to lead burning, and a lead burner rapidly becomes efficient in welding thin aluminum sheets. To facilitate the operat it is desirable to use a light weight b pipe.

Sheets between 1/16 inch and inch in thickness need not be bevel or flanged. Sheets 1/16 in. thick under should be flanged to a height 1 to 1½ times the thickness of metal. Clean the work thoroughly leave it bright along the line of w For quantity work. the manufacture sets of good heavy clamps will repay the outlay, and will help sec sound, neat work.

Preheating of sheet aluminum p to welding is only necessary occasion and then only to counteract moveme of the plates due to expansion. Dra aluminum wire must be used. W work is flanged no filler is necessary

A sheet aluminum flux must be ployed. The flux must not contain or alkali which might have a corrod effect if traces were left in the body the weld or on the surface of the she When used dry it is applied by dipp the heated welding rod into the pow when sufficient will adhere for appl tion at one time. Some fluxes can used wet or dry, but before applica by the wet method is tried, assura should be obtained from the source supply that the flux is suitable to used wet.

To use the flux in a wet form, i mixed with clean water in suffic quantity to produce a cream consiste mixture. To apply, use a piece of cl rag or cloth, dip in the flux and ap along both edges of the metal to joined; let the flux be applied at l ⅜ inch away from the line of weld. effectually removes the surface ox Then apply a second coating with small, stiff brush. Any further flux quired to obtain uniform flow of m can be added by dipping the weld rod in the mixture.

Execution of Welds.

Careful regulation of the blow flame is necessary. A slight excess acetylene is recommended. Avoid tact between the metal and the w cone of the flame. It will be found the first fusion of the metal takes s time, due to loss of heat by conducti and on this account the rate of welc will increase as the work progresses as the edges ahead are gradually hea by conductivity.

For sheets 1/16 inch thick fusio obtained before conductivity has time to diffuse the heat. With thic sheets conductivity absorbs a great of the heat and a larger blowpipe must be used in order to produce r fusion and prevent oxidation which take place if the weld is made slo With sheet aluminum, expansion t bles are not so difficult to deal with a the case with iron or steel, due to

Determining Pressures Exerted By Cutters

A New Device Which Tells At a Glance The Pressures Exerted On The Various Parts of a Milling Machine—It Also Shows Difference in Pressure Exerted With Cutters of Different Form.

VARIOUS devices have been designed from time to time for determining the pressures exerted by a milling cutter on the various working parts of a milling machine, but up to the present time there has been no mechanism which could be relied upon to give accurate readings of these pressures so that the designer of milling machines as well as the designer of fixtures and milling cutters for use on them has been very much in the dark. It has long been recognized that accurate knowledge in this regard would also be a material assistance to the designer of machine parts, which are to be built, because in the final analysis, the pressure of the cutter is first exerted on the piece itself and transmitted to the fixture and then to the milling machine.

Another element on which there is practically no existing knowledge is the difference in pressures exerted by cutters of different form or different design when taking duplicate cuts. It is true that a carefully calibrated machine equipped with a direct connected motor drive and a meter provides the means of determining the difference in horse power consumed by various cutters, but means are entirely lacking for separating the vertical thrust, the horizontal thrust, and the longitudinal thrust, and thus determining the pressures in these three directions. Also, with different combinations of feeds and speeds, the efficiency of the milling machine varies, and it is therefore important to have the means of determining the actual cutter pressures entirely independent of the efficiency of the machine or any part of its mechanism.

In order to attain this object, the Poliakoff Dynamometer was devised. The accompanying illustration show it as it is now being offered by the Cincinnati Milling Machine Co. This Dynamometer provides means for reading the pressures exerted on any milling cutter while at work, in two directions, the reading being taken direct from the dials shown.

FIGS. 1 TO 3—SHOWING THE DEVICE IN USE.

Fig. 1 is an illustration of the Dynamometer. It consists of a working table which is supported by a base plate, which is in turn bolted to the table of the machine. Fig. 2 shows the Dynamometer in place on a very large miller, taking a heavy cut in steel. The vertical downward or upward pressure of the cutter is read direct from the right hand dial. The longitudinal pressure of the cutter is read direct from the left hand dial. These are the pressures with which the designers and users of milling machines, as well as milling cutters are most concerned. However, if it is desired to also obtain the crosswise pressure, that is, the pressure in line with the milling machine arbor, as for example, if it is desired to determine the end thrust pressure, of a spiral milling cutter or a face milling cutter, the dynamometer can be mounted crosswise on the table, as shown in Fig. 3, and the pressure is read from the right hand dial.

The work platen of the dynamometer is supported at each end by a wide "Emery" plate fulcrum, their lower ends resting on two levers which carry a definite portion of the vertical load on the platen to an hydraulic chamber placed centrally under the work table. This chamber is connected with the left hand gauge which is graduated by trial in terms of the vertical load in pounds.

The horizontal load is transmitted through bars which are flexible vertically, to the crosshead seen at the right in Fig. 3, and this crosshead transmits the load to the hydraulic chamber seen between this crosshead and the end of the main frame of dynamometer. This chamber is connected to the right hand gauge by the pipe shown. Heavy springs are used to put initial loads on each chamber so they will show loads in either direction.

The "Emery" plate fulcrums carrying the loads to the levers are so constructed as to be rigid against vertical and cross loads, but flexible to longitudinal loads and the bars to the crossheads are flexible to vertical loads so neither system interferes with the action of the other. Guards are provided

Queenstown--Chippewa Power Project Is Visited

Even On A Short Tour The Magnitude Of The Work Is Apparent—Seldom Does A Single Job Embrace As Many Branches Of The Engineering Trades As This One—Huge Shovel Is Employed.

by J. H. MOORE

A STUPENDOUS Engineering Undertaking." "A sight never to be forgotten." "Something of which Canada can feel justly proud." The above opinions are but three of the many expressed by the party of engineers and executives who viewed the Queenston-Chippewa development on Friday, July 22nd, under special arrangements made by the Ontario section of the American Society of Mechanical Engineers.

Seldom is a task undertaken that embraces so many engineering problems as the new power scheme we are speaking of. It is hardly necessary to state at this late stage of developments what prompted the scheme. Everybody knows that the water will be brought in from the Niagara River, pass through a huge canal, later creating an enormous amount of power by its very volume. The problem of cutting a canal out of solid rock was itself a great one but practically every engineering trade enters into the successful completion of this project. The mechanical, electrical, structural and hydraulic branches are the chief ones interested, with the transport, and housing problems coming as secondary, yet important considerations.

Important Figures.

Before proceeding with the story of the trip itself, we will briefly review the more important figures connected with this great power scheme. When completed the power plant will consist of 9 units with 500,000 h.p. The effective head on the water is 305 ft., and the capacity of each power unit is 55,000 h.p. The length of the river section is four miles, and the length of the canal 9 miles, making 13 miles in all. The cut in both rock and earth is enormous, being 72 ft. in the earth and 85 ft. in the rock. The concrete water channel is 48 ft. wide, and under normal operations the depth of the water in this channel will be around 30 to 35 ft.

The maximum velocity in the canal will be 10 ft. per second, and the forebay, which is 1,000 ft. long, widens from the standard 48 ft. canal section to 500 ft. at the gate house. The penstocks used are 16 ft. in diameter, and not only is every joint riveted, but it is welded as well.

The power house when completed, will be 600 ft. long and 185 ft. high from its base. They figure the total earth excavation will be 13 million cubic yards, and the total rock excavation 4 million cubic yards. Work was really commenced on this project in May, 1917, and since that time great progress has been made.

To illustrate the detail necessary in a project of this kind, we will review very briefly some of the arrangements necessary to carry on the work. Seventeen highway and railway bridges have been built, two dredges and 14 shovels are used, also a cableway excavator. The writer viewed with interest the largest electric shovel ever made, working like a trojan on the job. Each bucket full means 8 cubic yards of earth and rock, and in some cases the material is lifted as high as 80 ft. Three trips of this shovel and a dump cart is full of material.

80 miles of railroad track have been laid, and over some of these lines pass more traffic than many a line owned by a large railroad company. 24 electric locomotives are used, 26 steam locomotives, and over 320 air dump carts.

The various concrete plants have capacities as follows: The crusher plant has a daily capacity of 3,000 cubic yards, the sand storage a capacity of 100,000 cubic yards, with a stone storage capacity of 250,000 cubic yards. There are 9 stationary concreting plants, 4 moveable paving plants, and 9 moveable lining plants.

Compressed Air.

The compressed air wants are well looked after, there being some 26 units electrically driven, which provide 30,000 cubic ft. of free air per minute. Over 500 temporary buildings are erected, and there are five camp districts for employees, providing accommodation for 6,000 men. With few exceptions electric power is used to drive the machinery at work, and the normal load for constructional purposes is 10,000 K.W.

Leaving these amazing figures to sink in, we will proceed to tell the story of the actual visit. The first place inspected was the power house. Here was to be seen some wonderful concrete work, both in the building itself and in the draft tubes, and ice chute provided. The form work on some of this work is nothing short of marvellous and shows what really can be accomplished with concrete. Without dwelling at length on any particular part of this portion of the plant, the party viewed the turbines, and various electrical units in connection with it. The penstocks with their massive proportions and extreme height came in for quite of lot of comment, and the men working on the face of the solid rock looked like mer scrambling to and fro.

After dinner the screen house w spected together with the wonderf tem of handling the pouring of co The method of transporting the vio materials used is wonderful. Con yors are used for everything. Centr sta- tions distribute the prepared mate al the different parts of the job, an on started, the flow is continuous un th particular portion is completed. T pouring tubes around this job are m numberless, and they are control gates operated at some central sp the case of the sand and stone, t y to a storage station, from there mixer or to some subsidiary poi in the case of the cement, a co e takes it direct from the car to th va ous mixing plants.

Change in Shape.

From this point on the party s ppe numerous times, inspecting the c al different points. At one porti canal channel changes from a t e. dial shape to a rectangular sh vice versa, as you would prefer. is where the old bed of the Niagar i crossed, and instead of a rock c portion is an earth fill, this fact a ing for the change in shape. Th crete work is so arranged that th again gradually assumes a rect section as rock is once more me

At another point in the canal, tain necessary curve has been ured out that the heat loss suff winter by the friction of the wat sing round this curve will preve ice sticking to the side of the c Readers of course will not care t to how his was arrived at, but i how much care has been exerc the preparation of the canal.

When completed the channel w a gradient of 1 ft. per mile, water will flow at a rate of about per hour. At first only two pow will be installed, and a flow o 6,500 ft. per second will be all required for these units.

In some of the concrete work canal channel portable forms a this being on the trapezodial portion. These forms are merely on top, the concrete poured, twelve hours the form can be lifted. For the main channel, the rectangular shape, special c pouring machines are used, these steel forms on either side which the correct distance apart, and

right from the machine, which is self contained. This machine runs on portable tracks on the bottom of the canal channel, and it is a treat to see it work.

The method of blasting rock is particularly interesting. Portable air drills go down for a depth of between 20 to 30 ft. in the solid rock, and holes are drilled about every 6 ft. across the channel bed. After drilling, the various holes are loaded with explosives, "Forcite" being chiefly used, and the charge is set off electrically The huge 8 cubic yards electric shovel then comes along and bites right into that depth.

The dredge "Cyclone" works away at the inlet to the canal, clearing away the earth, so as to allow the proper volume of work to pass through. In fact, to tell the tale properly and in detail would take a volume in itself. Even the huge stone crusher could take a lengthy description. There it appears, a massive mass of machinery, nothing to see inside, but crunch, crunch, crunch, it goes on, eating rocks and breaking them up like we would an ordinary chocolate. There is a spirit of romance to the whole venture, and one cannot help but feel the thrill of at least having been such a wonderful work being performed.

Col. Ellis was the chief guide, being ably assisted by Mr. Tobias, one of the designing engineers on the work. Twenty-one took advantage of the trip, these being H W. Price, Professor of Electrical Engineering, University of Toronto; W. F. Sutherland; Professor Gilchrist, of the Physics Section U. of T.; G. M. Smith; L. Tolson, and J. H. Moore, all of MacLean Publishing Co.; Col. A. D. Lepan, Supt. of Bldgs., U. of T.; Mr. Bradbron; Mr. Lewis, Supt. Machine Shop, J. Inglis Co.; Mr. Quesnell, boiler inspector; Mr. Howard, John Bertram and Sons, Dundas; Mr. Graham of the same firm; Prof. Angus, professor of Mechanical engineering, U. of T.; Harry Angus, constructional engineer; Robert Angus, Senior, retired constructional engineer; G. H. Raitt, Massey Harris Co.; Chester B. Hamilton, Jr., Hamilton Gear & Machine Co.; Mr. Crane; Mr. Boswell, and Mr. Moody of Powley & Townsley, Toronto.

WELDING ALUMINUM.

(Cont'd from Page 32).

Get that the high conductivity of the metal tends to even up the distribution of the heat in the whole.

Owing to the high conductivity of the metal and consequent even distribution of the heat, contraction does not as a rule cause cracking. Remember the metal is fragile at temperatures near the melting point and should therefore be carefully handled while cooling, which should take place slowly and away from draughts. Do not be in too great a hurry to remove clamps. After the work is cold wash away with warm water any traces of flux on the surface. Flux might, if left on the surface, have a corroding effect on the metal and also would be injurious to paint work and cause it to scale. Cold hammering along the line of weld after the flux is removed is good practice; it gives texture and grain to the weld. A spring power hammer is good for this work if available. Scbsequent annealing will remove hammer marks.

PRESSURES EXERTED.

(Cont'd from Page 33).

so that any desired lubrication or flooding of the cutter may be used.

The Dynamometer has the capacity to withstand loads of 25,000 lbs. longitudinal, and also loads of 4,000 lbs. in the opposite direction, vertical downward pressures of 10,000 lbs. and upward pressures of 7,000 lbs.

The working surface of the working table is 16" long x 10" wide, and is provided with three T-slots. The height of the working table above the bottom of the base is 8". The total size of the base of the Dynamometer is 35" long x 14" wide.

It is obvious that the Dynamometer is extremely valuable for manufacturers of both milling machines and milling cutters, as well as for shops where milling operations are studied and given proper attention (as automobile plants, experimental shops) for laboratories and shops of technical schools and colleges, etc. Problems attending standardization of machines and cutters can be more readily solved with its aid. This instrument has proven extremely satisfactory and very sensitive under tests. Its uses are not confined entirely to milling machines. but it is equally adaptable for making tests on planers, shapers, and with slight variations, drill presses.

REFRACTORY CRUCIBLES.

The making of crucibles from highly refractory oxides has been further investigated recently. It has been found possible to make such crucibles without the use of the clay or binder, which tends to reduce the refractoriness of the finished product. Usually this is effected by preparing a portion of the oxide in a colloidal state by grinding it extremely fine in the presence of soda or other suitable dispersing agent, or even by precipitating it from solution. A recent method is to make crucibles with the use of water by tamping the plastic mass inside a fireclay mould lined with plaster-of-paris. When the mould and crucible are fired to a red heat, remarks "Chemical Trade Journal," the plaster disintegrates and permits the crucible, which is then fairly strong, to be removed from the mould. The crucible is then fired to a high temperature in order to give it the necessary density and strength.

It is difficult to imagine that this method is likely to be any improvement on the ordinary use of plaster moulds when a plastic paste has to be used. If, on the contrary, the refractory oxide is suspended in water or other fluid, and is cast in a plast rmould, h eereatmy is cast in a plaster mould, there may be some advantage in the process, though this at least is doubtful, and the destruction of the mould would make the process costly.

Still another method is to mix linseed oil with a refractory oxide and to shape the crucible inside a detachable metal shell, the crucible being then baked in the shell in an oven—a similar process to that employed in the baking of cores for castings. After the baking, the shell is removed and the crucible fired to a high temperature, which results in the burning out of the temporary carbonaceous binder and the sintering of the refractory oxides, thus forming a dense, strong, and highly refractory crucible. This method is less objectionable, and has, in fact, been used to a considerable extent in making special crucibles for certain steel alloys where clay could not be employed.

WATER POWER IN FINLAND.

An important factor in the industrial development of Finland is the exploitation of its wealth of water power. The potential output of power from hydro-electric sources. chiefly from waterfalls, is estimated at 3,000,000 H.P., to which the River Ulea and the rivers south of it contribute 1,200,000 H.P. A considerable part of this water power is owned by the State. Among the important water-power resources entirely or partly in possession of the State are the following: Vucksen Falls, 300,000 H.P.; Imatra Falls, 211,000 H.P.; River Ulea, 542,000 H.P.; Pyhäkoski Falls, 100,000 H.P.

The output from existent hydro-electric power plants is only 170,000 H.P.

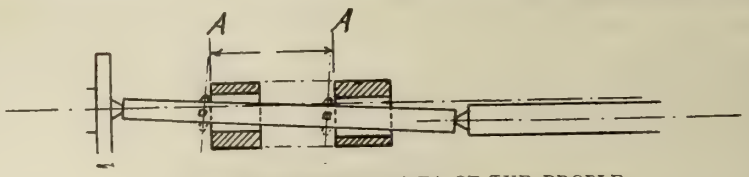
BOOK ON HANDLING

A most instructive illustrated book on tramrails as an economical means of handling and conveying materials has just been published by Cleveland Electric Tramrail Division of The Cleveland Crane and Engineering Company, Wickliffe, Ohio. A copy of this new book will be sent without charge to readers of this paper who are interested in cutting their material handling costs.

WHAT OUR READERS THINK AND DO

BORING WORK QUERY.

By JOHN S. WATTS.



Replying to the query under the above title, in Canadian Machinery, page 37, of the issue dated June 23rd, 1921, The answer is that the holes would be parallel, but slightly oval in shape instead of being circular as they should be. Further in this case, as each of the two holes are bored by a separate cutting tool, their center lines would be out of alignment.

As many machinists do not take any care to align the lathe centers doing a boring job, as they mistakenly think it makes no difference to the accuracy of the work, it will be opportune to prove the above statements, and show just what effect the lathe centers being out of line will have upon the accuracy of the work.

Referring to the figure accompanying this article, AB represents the center line of the lathe, and consequently the path of the center line of the casting being machined. BC is the center line of the boring bar when the centers are out of line, and therefore the center of the circle through which the cutting tool D passes. It will be noticed that while the cutting tool D, must perforce travel through a true circle, the plane in which this circle lies is not at right angles to the center line AB, along which the work is traversed. The result of this is that the hole bored by the cutting tool, as measured one plane EF, will be a true circle, but when measured on plane GH, at right angles to the center line of the casting, will be elliptical.

As the casting travels in a straight line past the cutting tool, each hole must be parallel throughout its length, so long as it is completed by the one cutting tool. or by a double cutter located on a single plane as EF, and unless the centers are very far out of line the amount of the variation from a true circle will not be important on average work.

For example, if we are boring out a 5-inch hole, with a bar 40 inches long, and the centers are ¼ inch out of line. The distance X in the figure will be $\frac{5 \times \frac{1}{4}}{40}$, or .03125 inches. As EF is 5 inches, the diameter measured along GH, will be $5^2 - .03125^2 = 4.9999$, or one ten thousandth of an inch oval. There will be always one plane in which both center lines AB and CB will lie, and the diameter measured at right angles to this plane, that is on a line vertical to the surface of the paper in figure, will be the full diameter of 5 inches.

MR. OSBORN'S IDEA OF THE PROBLE

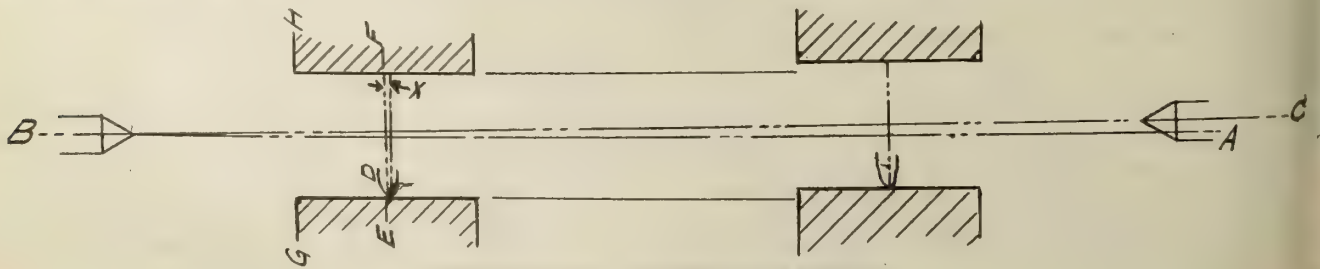
The area will vary with the diameter of the hole, and inversely with the length of the boring bar, that is if the hole in the above example was 10 inches, the error would be doubled; and if the boring bar was only 20 inches long, the error would be doubled again, the amount of misalignment of the centers remaining the same. It is clear then these dimensions are extreme, it is not necessary to exercise more than ordinary care to have the centers in approximate alignment.

In the example given in the query however, there are two holes bored, and each is machined by a separate cutting tool. A study of the drawing herewith, will show that these holes will be bored out of line with each other an amount equal to the misalignment of the centers, divided by the ratio of the distance between the centers of the tools, and the total length of the boring bar. That is if the tools are 20 inches apart, and the bar is 40 inches long, the centers being ¼ inch out of line would cause the holes to be bored one half of this amount out or ⅛ inch. It follows that when using a bar with two cutting tools in its length, such as is shown in the original query, it will be necessary to have the lathe centers in exact alignment.

BORING WORK QUERY.

By H. T. OSBORN.

In answer to Mr. James' boring work query in June 23rd issue. The lathe centers being out of alignment would not cause the holes to be bored taper. So long as all adjustments stay set and the tools hold their edges, the work would be affected to the extent of the center of the holes being out of alignment a amount to be determined as follows:—

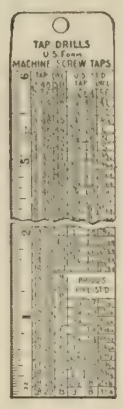


Find how much the lathe centers ar out, then set down in a simple propo tion sum:—The distance in inches b tween faces AA on accompaning sketc the length of the bar in inches; an the amount the lathe centers are out alignment in fractions of an inch. F example, suppose the bar is 36 inche the distance between faces AA 12 inch and lathe centers are out .015 inche

Then—36:12 = .015:x Solving, x .005 ins.

The lathe centers being out of li would of course throw the axis of t bar to a slight angle to the work axi This would, theoretically, cause t tools to bore the holes slightly ov and it would be interesting to know such shows up in actual practice.

MAGNETIC TESTING.



One of the committees of the Ame can Society for Testing Materials, h been carrying out an interesting inves gation, which has for its object the d velopment of apparatus which can used commercially for the non- destr tive testing of twist drills. The plan procedure is as follows: Steel, specia prepared by one member of the co mittee, is tested for homogeneity by magnetic method at the Bureau of Sta dards. The drills are to be manuf tured from this steel by another me ber of the committee under carefu controlled conditons, after which th will be tested again magnetically various members of the committee. F lowing the magnetic tests, the dri will be returned to the manufactur who is to give them a thorough mecha ical test.

THE SOLUTION AS JOHN WATT SEES IT.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

As already promised, we give two scales this issue. Of those received, we had four correct answers. Angus A. Smith, Mt. Forest, and B. Back, of the P. B. Yates Co., Hamilton, were the two picked out in the elimination test. George Land, Peterboro, and F. E. Regan, Hamilton, also had correct lists. We still receive letters stating that scales have not reached winners. Readers will confer a favor by writing us should they not receive their scales one week after announcement.

CONTEST FOR JULY 28TH ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1—A product that costs more, yet is said to be worth the difference.
2—Three good thoughts for mechanics.
3—Free opinion which will be unbiased.
4—Something which has five features.
5—How to handle cotton lint, or stringy material.
5—Something that does not depend entirely upon bulk or weight.
7—A product air tight under all pressures.
8—Something that modern practice has discarded.
9—An organization always at your service.
10—Something which has proved of value in the mining field.
11—A machine which requires no special fixtures.
12—Something said to do better work in less time.

These are Correct Answers for List from July 7th Issue:

1—John T. Hepburn, Ltd.
2—Bilton Machine Tool Co.
3—The Royal Bank of Canada.
4—The Warner & Swasey Co.
5—Algoma Steel Corporation, Ltd.
6—National Acme Company.
7—The Bristol Company.
8—United States Machine Tool Co.
9—Canadian Hanson & Van Winkle Co., Ltd.
10—Canadian Hart Products, Ltd.
11—Greenfield Tap & Die Corporation.
12—George Ellison.

Closing Date for This Contest is Aug. 11th

DEVELOPMENTS IN SHOP EQUIPMENT

SPECIAL GRINDER.

The Landis Tool Co., Waynesboro, Pa., have placed on the market a special grinding machine for regrinding all parts of automotive engines. Utility has been the chief feature aimed at. The crank carrying fixtures have been designed to handle crankshafts easily and all loose attachments such as chucks, dogs, blocks and so-called throw blocks have been eliminated. Work carry heads which are a part of the headstock and the footstock are equipped with three jaw universal chucks, to grip each end of the crankshaft. Bushings are not necessary. An indexing dial is used for locating the chucks for the different size strokes of crankshafts. The work carrying heads are centered and brought in line by use of locating pins, after which the machine is ready to receive the work.

The shaft is then placed in the three jaw chucks, brought in line and trued radially by use of the trueing device located on the top of the work rest. The chuck jaws are next drawn up fairly tight, not however, as tight as is necessary for lathe work. The trueing device is then removed and the work of regrinding proceeds. This operation is accomplished in from one to one and one-half hours for four throw shaft, and one and one-half to two hours for six throw shafts.

This machine will also grind all other parts of automotive engines with the exception of the cylinders cast en-bloc. The wheel carriage has power speed and all traverse speed changes are controlled by one lever. The machine is designed to carry a 24" diameter wheel with 5" belt for driving same and the wheel can be worn down to hole or safety point. The machine is driven with a small countershaft and requires 5 horsepower to operate. The chief features of this special machine are the heads or work carrying fixtures and the automatic balancing weights which can be moved in and out from the center according to size of crankshafts.

COMBINATION WORK BENCH.

The Meyers Machine Tool Corporation, Columbus, Pa., have placed on the market a combination work bench which is intended for use where a small machine equipment is required, such as in automobile repair shops, inventors' workshops, etc.

All the units are mounted on a table 39 in. wide by 78 in. long by 33 in. high, the top, sides and shelf being made of 1½-in. and the legs of 3 x 4-in. lumber. Two drawers are provided for holding small tools. The motive power is furnished by an a.c. electric motor, mounted on the shelf under the table, and delivering ½ h.p. when running at 1,750 r.p.m. on 60-cycle, single-phase current of either 110 or 220 volts. The motor is belted to the countershaft, which permits the use of the machines either individually or simultaneously.

The machine equipment consists of a geared automatic hacksaw having a capacity of 6 x 6 in.; a 10-in. sensitive drilling machine having a ⅜-in. chuck; a grinding head equipped with one abrasive wheel and one muslin polishing wheel, and 4-in. machinist's vise having hardened steel jaws. The outfit is complete with the belting, and weighs 750 lbs. when crated.

REVERSING TAPPING CHUCK

A new design of tapping chuck has been placed on the market by the John Chuck Co., of Milwaukee, Wis. The chuck is equipped with a five-point sensitive clutch, and it is stated that it will automatically release within a limit of .001 inch of the pre-determined depth of tapping. The reverse speed is in the ratio of 2 : 1. The internal gears all run in oil and the chuck is provided with an oiling device for supplying oil to the tap or the work. The body of the chuck is made of aluminum so that the weight is reduced to a minimum. Three sets of standard tap drivers and retainers are furnished with the chuck, and special drivers and retainers will be supplied when desired.

A Great Power Scheme

Another portion of this issue is a short description of a tour through the Queenston-Chippewa Development. What a fair idea may be gleaned from the story, the work itself must be seen to be appreciated. The science of engineering has reached a wonderful stage of development. Schemes such as the Chippewa project would be impossible were it not for the ingenuity of the various branches of the engineering trade. First of all we have the designers. These men are experts in the higher forms of mathematics and can tell with certainty what size, shape and strength everything should be. Next comes the various construction operations. Each department of engineering has its work. The rock drillers, blasters, dredgers, concrete men, electrical engineers, transport, hydraulic, and general mechanical trades all enter into the finished work. Each is equally important. One must work in harmony with the other if satisfactory results are to be obtained.

The machinery used in the constructional work on this project is nothing short of marvellous. Imagine an 8 cubic yard shovel a few years ago. Such a thing was unthought of. The shovels then in existence were considered quite large enough, but it would seem that the larger the job the bigger designers will build shovels. The development by no means ends with the shovel. All the mechanical means employed are of the very latest. Even the method of conveying the materials for the concrete to the work is perfect. There is no lost motion. Everything has been studied with a view to efficiency, and such a result has been obtained.

Canada can proudly point to their Quebec Bridge as a great engineering attainment, but for romance and vision, they will have a still greater cause for pride when the water flows into the canal of this great Queenston-Chippewa power scheme.

A Danger Easily Remedied

Coming in contact with a live wire, a Hydro lineman recently met his death in Toronto. Upon investigation it was found that he had not used the added protection of leather gloves over his rubber ones. The cause of death was also attributed to faulty gloves.

The fact remains the man is dead, and that he is not the first who has passed out in like manner. Forgetting for the moment that the lineman did not use his leather gloves how about the rubber pair?

It was proved that the gloves used had not been tested since June 2nd, although it is supposed to be a hard and fast rule that gloves must be tested once a month. It would be interesting to know who was at fault, the company, or the men. When men work with electricity constantly they have a tendency to become careless. "Oh, those gloves are all right," is a usual statement, and the fact that this particular lineman did not use his leather gloves proves that men do get careless.

What is the remedy? Someone suggests testing the gloves each day. This, to our mind, is hardly necessary. If every pair of gloves in use throughout Canada were tested each day, it would entail a considerable amount of unnecessary work. A better plan, if a month is considered too long a period, would be to test the gloves every two weeks. Personally we believe once a month sufficient, if the gloves are taken proper care of. We have on two occasions witnessed the testing of such gloves, nnd it is very thorough, 13,000 volts being passed through the testing apparatus. If a glove is weak or damaged, a hole is blown out at the weakest spot. The men at this work are extremely careful, and if the linemen on the job were half as careful of their gloves after they get them there would be fewer fatalities.

A very good emergency test would be for linemen to take their gloves top up; fold the top over once, then holding this firmly to seal the air inside, twist the glove slowly until all the air was pushed to the top. In the event of a flaw, the escaping air could be plainly heard. But all this is unnecessary if workmen will take the proper care of both their rubber and leather gloves, wearing the latter on all occasions where any object is liable to damage the rubber.

A Bonus Plan That Gets Results

THERE are Bonus systems of all kinds, but here is one that Edward Hungerford describes in the New York Evening Post. He speaks of the wage dividend plan in operation in the Eastman plant, this concern having about 18,000 employees. The first dividend was distributed July 1st, 1912, and since that time it has been paid yearly.

In this case the management regards a 10 per cent. dividend to stockholders as parallel to the employees' regular wage. Any earnings over this amount are considered as extraordinary and, to a certain extent, the common property of the stockholders and employees. An arbitrary division is made in which 35 per cent. of the extra dividend goes to the employees.

To illustrate how this has worked out, during 1911, 1912, and 1913, the extra earnings were 30 per cent., and 35 per cent. of this is 10.5 per cent. of the total extra earnings. This amount goes to the employees. The award is made on a basis of five years of service with the company. This does not mean that employees who have not been there for five years do not participate, but that they participate in proportion to the time they have been employed, as well as to their average earnings.

One employee with five years' service averaged $30 a week and received $163.80 on dividend day. If he had been there but four years he would have received $131.04, and if he had had but one year's service his dividend would have been $32.76.

Building An Industrial City—Not A Population

Business Is Simply The Supply Of Human Wants—Intelligence Essential To Business Expansion and Contentment—Community Schemes Are Good—Industrial Service Desirable—Labor Turnover Very Low

By HUGH M. BELL, Manager Chamber of Commerce, St. Catharines.

"THAT Civics and Commerce are linked up in no unmistakable way, and that Business is not something remote from all the other phases of community and national life, is the opinion of the directors of the Chamber of Commerce at St. Catharines, Ont. The day is past for all special regard for business as something sacred and not to be understood, and has arrived for the logical coordination of schools, homes, parks, playgrounds, hygiene and all the arts of living with the industrial possibilities of any community or country."

Business is simply the supply of human wants and as the standard of living advances, human wants grow, so business expands. Business is better where there is a high average intelligence than a mass population without culture. Compare Ontario's buying powers with that of Black Africa's, yet the blacks outnumber the whites four to one, at least. We in St. Catharines have determined upon a definite community program of work. It covers definite tasks to which the Chamber of Commerce of 500 members is pledged. It is remarkable for its breadth and has in the past six months of this year covered such phases as:—Playgrounds scheme, which removes children from the streets; bus line to outside points, which develops the trade territory; new public park in the artisan locality; an industrial survey which lists the industrial properties and improved transportation facilities.

On top of this we have had community dances, bands being in attendance; moonlight excursions; half fare weeks; and educative trade tours.

Industrial Service.

Definite data has been secured on wage costs—land costs—freight rates, city taxes, lake freight rates, floor space, factory sites, and in the past six months, over sixty manufacturers (or promoters) have met the Board of Directors of the Chamber of Commerce and explained their propositions. We do not endorse stock promoting campaigns, or stock selling industries. It is the belief of good business men here that the city has been developing the sort of atmosphere essential to industrial stability.

We place "factory grabbing" last, because housing and right conditions are the first care of any community organization. Yet from following out this policy we believe we are in a position to serve industry with a better conscience than on the old poetic "town boosting" stuff. We give no bonuses, offer no bribes, tell no lies. We sell our city on its merits. are conscious of its demerits and by the co-operative effort

HUGH. M. BELL

of our members in the Chamber are solving them. Business needs all things, not just one of them—a free site. Free sites like charity cover a multitude of sins. Our land is valuable because it has the town advantages of rail and canal. We do not desire it to become a graveyard of empty factories. therefore, propositions that cannot make the grade do not get free chunks of it. On the other hand, a going concern temporarily embarrassed has no reason to fear lack of support.

Over sixty different concerns have been in town since January, 1921. Two have purchased land and are awaiting the lowering of costs. Options are held on several other properties, awaiting certain signs of a trade revival to start up. A rubber tire plant is going into operation in June. Many concerns were passed up, neither they nor we could see eye for eye, and with the best of feeling they went elsewhere.. Tragedies followed some of them, and in other cases the law.

When we make a mistake we admit it, but do not cry over it. It is the duty of the Chamber of Commerce of any city to offer such service and protecti[on] it is invited to give. An industrial [com]missioner is not a miracle worke[r] is an analyst whose job it is to ge[t] right sort of industries into the [city] area for them, because afterward he must live with them or the indig[nant] citizenry whose property values [have] been disturbed.

"Getting a factory first" and "a [good] place to live in afterwards" is a fal[lacy] One must accompany the other. The responsibilities are so great that [slums] populations are a result. Foster [civic] conditions, help make home owners [of] one company does here at easy r[ates] think in terms of social well being [and] get "uplift," be human, kind, and [the] city will win in the long run against its "booster" neighbor with unp[aved] lanes, rickety babies, stinking ho[les] poor parks and little civic spirit.

Te labor turnover in one plant [here] has not changed twice in ten years In another the Manager and Vice-Pr[esi]dent knows all his men by their [first] names. He polled the highest vot[e for] the Board of Education. We have [had] no big industrial deadlocks in the [city] in ten years. We are planning to [meet] trade revival with a contented com[mun]ity, and fifty-five per cent. own [their] own homes.

THE SPEED CHECKER.

As a means of checking up or [the] speedster a device has been invente[d by] Col. Charles Gore, of Los Angeles, [it] consisting of an attachment secur[ed] the front of the car, which is sup[plied] with three lights. As soon as th[e car] commences to move, a white lig[ht is] thrown into action. This continue[s] til the rate of travel passes the [limit] of the city ordinance, when the [white] light comes on, showing that the [safe] try rate is being used. If the d[river] exceeds that the red light flashe[s a] signal of danger to all within seein[g] tance. Since the mechanism can n[ot be] manipulated from within the car, [it is] impossible for the motorist to f[ool] his speed. These lights lock auto[matic]ically; hence if a driver breaks the law for only a few minutes the [red] light will continue to burn after h[e has] slowed down to the white range. [Should] this means a traffic officer or any[other] server outside the car can tell [at a] glance what has been the rate of s[peed].

MARKET DEVELOPMENTS

Looking For An Improvement In The Markets

Pittsburgh Says That In Some Cases The Demand For Steel Is Slightly Better—Scrap Metal Markets Are Still Away Off—Price Is Not A Determining Factor In Present Transactions

THE steel trade has reached the point where it is trying to look hard enough to see in passing events the start of better days. Others are working from the standpoint that things are bound to turn for the better if they move at all, as they are about as bad now as they can be.

Pittsburgh reports that inquiry is better for steel in some places, although there is no attempt made to turn this into a claim for all-round betterment.

Prices are not showing any tendency to hold firm in any of the lines. Many of the schedules are more or less nominal, as the buyers are still very much in control of the market, and in many instances they are not hesitating to take full advantage of their position.

The scrap metal market shows no improvement. Dealers state that business is about as low as could be imagined, and it would pay them much better were their yards closed up for the present.

PITTSBURGH TRYING TO SEE START TOWARD A BETTER DEMAND FOR STEEL

PITTSBURGH, July 28.—In last letter it was said that a turn had probably occurred in the matter of the volume of demand upon the steel mills. In the past week there has been some confirmation of this view. Some mills report a larger volume of inquiry, also somewhat larger bookings. Other mills assert that they see no improvement. None say that conditions have grown worse. It is a very delicate matter to see an improvement in the volume of business for the reason that the volume was so small to start with. That is, if mills had a demand equal to 80 per cent. of capacity and the demand increased to 90 per cent., the difference would be easily noticeable. It would be an increase of 12½ per cent. on an 80 per cent. demand. If, however, demand was 16 per cent. (and it has been something like that, not much more at any rate) and there was an increase of 2 per cent., that would only be to 18 per cent. and the difference between 16 per cent. and 18 per cent. would not be very conspicuous.

In other words, the business was so extremely light that the beginning of improvement is necessarily very gentle indeed, yet it is absolutely necessary that the thing start with a beginning.

The improvement is most noticeable in the case of sheets, for which there is a demand from practically all sections of the country and in nearly all classes of consumption or distribution. The independents have been getting more orders and the leading interest has been getting some, but of course its increase is chiefly in specifications against contracts, which are reported as much better. The orders and specifications are largely for single carloads, with the specifications quite mixed. In merchant steel bars there is a similarly widespread demand, though little increase in total tonnage, with also the showing of specifications being widely distributed. In both commodities the evidence is that jobbers and manufacturing consumers are running out of stocks and must order to fill in. As stocks go down farther the orders will, presumably, have to be larger.

In plates and shapes there is little or no improvement. In standard steel pipe there is reported a much better distribution by jobbers, suggesting that there will soon be heavier demands upon the mills. Wire and tin plate are out of season, show no change, and could not be expected to show any at this time.

Consideration of all the information obtainable indicates that the liquidation of stocks of steel in the hands of jobbers and manufacturing consumers, and the liquidation of stocks of manufactured goods in the hands of manufacturers using steel, has proceeded to such a point that these buyers must call upo the mills for somewhat more steel than formerly. The steel market shows no indication that the amount of activity in business generally has increased, nor does it show any increase in railroad buying. Those are favorable developments that are still awaited. The point is that the demand upon the steel mills was below a normal relation to the amount of business generally, or the degree of industrial activity as a whole, by reason of the stocks that stood in the way, and it appears that now the demand for steel has begun to work up to a normal relation. This readjustment may bring steel demand up to 30 or 40 per cent. of capacity instead of less than 20 per cent., as it has stood since late in June. When business generally improves, when more construction work is undertaken and when the railroads get in shape to buy, there will be further improvement. Not a great deal along such lines is expected within the next few months.

Steel Prices.

The competitive character of the steel market is still more clearly established. There are few, if any mills, except some small mills that are closed completely, that will not name a special price to get an order of special attractiveness. Many make the rule that anything from two carloads up is a specially attractive order. Whatever price the mill has as its "regular" price is likely to be the price only on single carloads. The price may or may not be the price publicly announced early in July, when the mills made certain formal "reductions." On plates the July 5 price was 2c, but some mills would probably do 1.90c even on a single carload, so that in this respect the formal price has practically disappeared. It has disappeared in another respect, in that Pittsburgh basing is wholly abandoned, as to plates, and it is disappearing as to some other commodi-

ties. Chicago mills have quoted as low on plates, f.o.b. their mills, as Pittsburgh mills have quoted. It is approximately as easy to buy plates at 1.85c Chicago as at 1.85c Pittsburgh, instead of there being a differential of .38c, the amount of the freight.

The July 5 prices of 3.50c on black sheets and 4.50c on galvanized sheets have practically disappeared in favor of, say, 3.40c and 4.40c on single carloads and lower prices on really good sized orders.

The rank and file of buyers are not showing any keen interest in steel prices. They are buying simply from hand to mouth, and buy only when they can distribute the material at once or when they have sold manufactured products against the steel desired. Prompt shipment buyers are not only interested in but insist upon.

The probability is that the period of formal or clear cut reductions in steel prices has ended, and that any further declines will be gradual and by small amounts at a time. Prices may recede by an average of 50 cents to a dollar a ton per week for several weeks. Pre-war average prices are unlikely to be reached within a few months, while pre-war low prices could not be reached for years. The steel mills are not thinking about price advances in future. What they are thinking about is getting costs down and they hope to get them down year by year for many years.

Wages.

While several mills in the Pittsburgh and valley districts reduced wages early in July, putting the common labor rate at 30 instead of 37 cents, the Steel Corporation is still on the 37-cent basis, together with a few remaining independents. This reduction will no doubt come in time. Some steel mills observe a feeling on the part of steel buyers that they cannot have any confidence in whatever steel prices are quoted until wages are down, on the basis that if a steel mill can quote a certain price when paying certain wages it will be able to quote a lower price when it reduces wages. A 30-cent rate for common labor is likely to become established for the longer future. This would compare with 19 cents before the war and 13 cents in 1898.

Pig Iron.

In most districts pig iron prices have sagged a trifle in the past week, while the Buffalo market has had rather a sensational decline. There is a report that one lot of foundry iron sold at $18, Buffalo. The valley market is down $1 on foundry and 50 cents on steel making grades, being now quotable as follows: Bessemer, $20.50; basic, $19; foundry, $19.50. Freight to Pittsburgh is $1.96, but furnaces nearer Pittsburgh would probably sell at lower delivered prices than the valley market, plus the $1.96 freight.

POINTS IN WEEK'S MARKETING NOTES

Pig iron prices in Pittsburgh still continue at low ebb. Some small lots are still going at $23.50 to $24.00, furnace, for No. 2 plain. Copper free, low phosphorus iron is featureless.

Chicago reports that foundry iron activity has somewhat improved. No large tonnage is in evidence, but the small orders for pig iron have increased in number. One deal for three carloads of resale foundry iron at $21.00 delivered, is reported.

New York states that Buffalo and other eastern Philadelphia furnaces are competing for any attractive pig iron offers that are available. In some cases the silicon differentials are being disregarded entirely. Inquiry in this district is greater than it has been for some time.

In Cleveland the prices are about as low as dealers expect to see them. Cleveland iron is quoted at $21 to $22 base furnace. Enquiries are better all around and actual orders are more than a mere possibility.

Scrap is still in the dumps, and no noticeable improvement is looked for at present. The majority of mills now in operation are well supplied, therefore it can be expected that sales will not climb to any appreriable extent for some time to come.

The recent cut in wire and wire products have not increased business to any extent. Present activities are mostly confined to the revision of outstanding quotations new enquiries being few and far between.

The sheet market has been visited with a price cutting wave which seems to have petered out at last. Keen competition is in evidence in this market, but the amount of buying going on is no real test of the market.

In the steel market the reaction following the new prices has been very disappointing. Buyers seem to be holding off for a further drop, the recent reduction in wages seeming to make them imagine another cut is coming. Leading steel manufacturers say that the new prices are as low as they should be. In fact some state that should labor go down to 25c per hour, prices should drop no lower until the industry obtains the benefit of lower freight rates.

WANT RESULTS FROM NEW PRICES

That Seems to be the Attitude of the Trade—Business Done is on a Small Scale.

TORONTO.—It is not unusual to find dealers who base their opinions on future business on peculiar facts. For instance, one often hears the remark in the machine tool or steel market that business is bound to improve because it has got to the point where it would be hard to imagine it approaching anything nearer stagnation.

There are bright spots here and there, but they are local conditions, and no one has the nerve to rise up and claim them to be a reflection of general changes.

More tariff regulations are coming into operation on the first of October, and the trade is studying the effect of some of these, especially as they will apply to the machine tool business.

Stamped With Origin.

One provision is that every part brought into Canada must be stamped with the name of the country in which it is made. The idea is that this will do away with deception regarding the origin of any machine or part of a machine. When discussing the matter with a local machine tool dealer, this paper secured his views on the matter, to this effect: "Suppose I bring in a machine from United States. We handle a good many American lines. In three or six months there may be a part needed for purposes of repair. It will be a peculiar business if every one of those pieces of that machine will have to be stamped 'Made in United States,' and yet as I understand the new law that is what it will mean. Will these firms go to the trouble to comply with that ruling just for the benefit of the Canadian trade, as I do not believe it is asked for elsewhere?"

Little Talk of Prices.

Another tool dealer is quite sure that prices have little or nothing whatever to do with sales now. From that he figures out that the reduction of prices is not desirable now because it will not bring any business into the market.

"Here is a case that will show what I mean. I have in mind two tools made by different firms. For a long time these sold at $3,600. The trade knew them both and there was very little difference between them as far as actual work was concerned. Of course each tool had its talking points, but when a man was fitted up with either of them he had a good machine. One firm started a few months ago to let down the price in order to see if they would get

...ual. They were in close touch with ... force in Canada, and the first ... brought them to $3,400. Within ... weeks they had come down again to ... and to-day the price is around ... It is just as good a machine ... ever was and it is probably costing ... as much money as ever to turn ... because there are such a few ... through the shop, but there is no ... difference in the sales. We are advised ... there is nothing to show where the ... reduction has brought the sale of a ... machine. We are coming more and ... more to the belief that it will be time ... to arrange new prices when the buying public show some signs of coming along and taking hold again."

In firms where both wood and metal working machinery is handled, the opinion seems to be that the former is leading in sales.

Waste Revisions Hold.

The reductions recently announced on both white and cotton wastes are being generally maintained. No further price revisions have been recorded, and dealers state that few changes, if any, are now expected. Market conditions are generally reported fair, with some signs of a more optimistic tone developing in the trade.

A slight increase in the number of inquiries of steel has been reported, but only a proportion of these have developed into new business. Many of such inquiries are generally calculated as movements to sound out the market tone, and the buying prices. The quiet period, therefore, is stated as continuing, with the recent announcement of price recessions on the primary steel markets, being reflected in local circles by one or two gradual reductions. Last week, both band and hoop steel quotations were lowered, and reduced prices are now recorded on spring steel.

Some lower prices were announced in the sheet markets and merchants are awaiting the results of these revisions. Whether business will respond to these more attractive levels, is considered contingent upon the degree of business activity, but it is stated that any worth while reduction is likely to uncover buyers. The formal announcement of a lower scale of steel prices recently made by the Bethlehem Steel Company, has not directly affected local conditions, due to the fact that such nominal recessions, were only in reality bringing the official prices down to levels which were already in existence on the primary markets. The chief object in such a formality is stated as being a desire on the part of the steel mills to relieve the industry generally from the appearance of securing higher prices than were really being obtained. No new development has been recorded this week in sheets and plates, the prevailing tendency being an abnormal proportion of inquiries compared with the current volume of business.

Non-Ferrous Metals.

Conditions in the ingot metal markets are still described as listless, and very little trading has been recorded. Quotations on the local markets are nominally unchanged, but a little variation is recorded in conditions on the various metals, as follows:

No immediate improvement in the copper market is looked for, but it has been pointed out that the formal reduction in prices, recently announced by various steel mills, is regarded as a favorable development, due to the fact that high prices on iron and steel have had their effect in retarding purchases of copper. Signs of a more optimistic tone developing, are therefore apparent, but local quotations remain unchanged at 17½ cents.

The tin market has recently been quiet, with prices practically stationary. The recent reduction in quotations on tin plate had no effect, as the new price has previously been in effect through independent activities. The outlook for any marked improvement is not considered bright, and consumers are not purchasing as previously. The range in local quotations of from 37 to 38 cents is still evident.

A firmer tone has recently been recorded in the lead markets, and reports from southern centres indicate that inquiries have been more numerous. The increase in the number of inquiries appears to be the chief factor at this time. Prices locally are still maintained at $6.75.

While the dull trend still prevails in spelter conditions generally, yet the opinion has been expressed that even if the present small demand shows no material improvement, the current prices are expected to remain firm. The desire to sell at any costs among producing circles, in order to move stocks at a time when there was no particular market evident for the metal, is what is quoted as the cause for the recent drop in quotations. The price of $7.00 still prevails locally.

This market is virtually at a standstill, as far as demand from consumers is concerned, but current quotations are unchanged. The local price is from 8 to 10 cents.

The movement on aluminum has shown no improvement whatever, but prices are being maintained at previous levels. The local quotation is unchanged at 30 cents.

Pig Iron Markets

Pig iron prices in Pittsburgh are about the same with very little demand even at the present price. In Chicago the output is limited as there is now only one furnace operating on merchant iron exclusively. Another furnace is chiefly employed on Bessemer for an allied company, making very few casts of malleable or foundry. The buying is very limited, and what orders exist are for small quantities.

In Philadelphia the same condition holds good. Once in a while someone places a half decent order, the trade feels the turn has been reached, then away flops the market back into its featureless groove. In Boston 200 tons looks like a good sized order. Of course it isn't—but dealers are glad to get even that.

Buffalo reports that enquiries are better, but that this is as far as the improvement goes. In actual sales the result is poor. Dealers in this market are not very hopeful so far as any immediate improvement is concerned. There are several reports of $19.50 sales, but these figures cannot be verified.

The market is still weak in New York. A flurry occurs occasionally, but it does not last. Enquiries come in all right, but orders do not always follow. Dealers feel that the most encouraging feature to them is the fact that stocks of foundrymen are being so reduced that when sales are made they call for almost immediate delivery.

Scrap Metal Markets

The scrap market in Pittsburgh still remains dull. Quotations show no marked changes except that cast i
borings are a little lower than bef
Sheet bar crops and heavy breaka
scrap are also somewhat lower than

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

CANADA AND BRITAIN CAN WORK TOGETHER TO GOOD ADVANTAGE

SPEAKING on the subject of "Reciprocal Trade With Canada," Sir Peter Rylands, President of the Federation of British industries, comments as follows:

"In the first place, the United Kingdom needs Canadian products. The British Isles are dependent upon supplies from overseas both for raw and semi-manufactured materials, to keep its factories working, and for food for its 50,000,000 inhabitants. Great Britain can never hope to supply her own requirements, either in the way of food or raw materials; both must be imported from abroad.

Canadian Products Needed.

"Canada, one of the world's greatest existing granaries, is in a position not only to supply food for the teeming population of industrial Britain, but to a large degree those raw materials of which the industries of the north stand to need. The Dominion is one of the richest potential sources of minerals and timber. Her vast natural wealth in iron, lead, copper and silver, is still, to all intents and purposes, unexploited. She is already the world's largest producer of nickel, corundum and asbestos, while her wealth in timber is larger than that of any other country in the world.

"All these products are needed by Great Britain. From what source could they be more conveniently obtained than from Canada, which of all the countries within the Empire is within easiest touch of the great west coast ports, such as Manchester, Glasgow and Liverpool. The United Kingdom must pay her bill for food and raw materials by exporting her manufactured articles, of which Canada, as a country still relatively undeveloped, stands in need.

"This raises the second point, that Canada needs English goods and English capital for her development. The industrial prosperity of Canada will depend to my mind, upon her successful resistance to foreign competition, which may be confidently expected to become increasingly fierce as the years go on. Standing alone, the danger exists that the growing industries of the Dominion may be swamped by the activities of her competitors. This danger may be appreciably minimized by the British Empire presenting a united front to competition from outside it. The Empire is able to do this owing to the fact that it is in reality an economic entity; in other words—the requirements either in raw materials, foodstuffs, or manufactured goods of one part of the Empire can in almost every case be supplied from some other member within the Imperial comity. Everything that can be done to strengthen inter-Imperial commerce must react to the benefit of Canada.

Should Erect Factories.

"Any increase in the exchange of goods between the United Kingdom and Canada will make for a better understanding and better relations, but manufacturers in Great Britain can also help in the development of the Dominion by investing capital in Canada. One of the most important ways by which this can be effected is by the erection of British factories there. The United States has already recognized the importance of such action and it is significant that in 1919, in the city of Toronto alone, twenty-one American branch factories were opened as against one British. In fact, it is only to be expected that the United States, favored as she is by her geographical juxtaposition, will do everything in her power to exploit the great riches of the Dominion.

"Difficult though it may be at the present moment for industrialists in the United Kingdom to find the capital necessary for opening up works in Canada, it should not be lost sight of that the chance of securing a share for the United Kingdom in the great industrial future of Canada, which exists to-day, may be gone to-morrow.

"From both standpoints, therefore it is to the best interest of both nations that every effort should be made to strengthen the commercial ties between them."

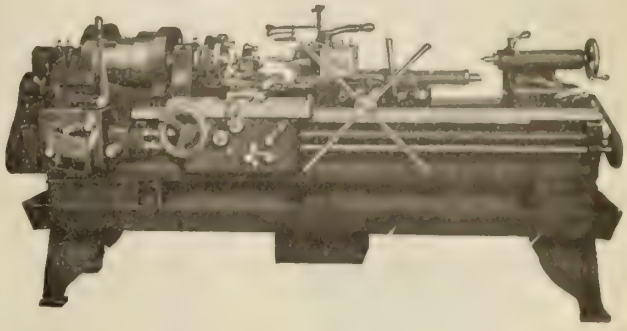
MOVEMENT TOWARDS NORMAL LEVEL EXISTS

Export Trade Impossible at Present—Rates of Exchange are Getting Better—Once This Difficulty is Removed Things Will be Better.

Speaking to F. W. Field, H. M. Trade Commissioner for overseas trade, on the subject of exporting, he said that at no previous period since the beginning of the war has the position of United Kingdom metal products industries been in gled, for the time being, all those in-between the coal miners' organization and the mine owners, occasioned by the proposed reduction in wages, has strangled, for the time being, all those industries depending on coal, which include practically the whole range of the trades under this heading, as well as transport and other vital services.

"It is apparently agreed by all the best informed authorities," he continued, "that the steel and allied industries cannot afford to pay the price for coal hitherto asked, and make even the barest margin of profit. The result has been that for some time prior to the dispute now in progress, Continental steel was (and still is) being imported for finishing processes. It all comes down to the basic fact that in order that these industries may exist in this country cheaper fuel must be available.

"One natural development has been to turn attention to oil as fuel. Fortunately there is no lack of this commodity and it is being used wherever possible as fast as plant can be converted.



"With such conditions in the leading industry it is of little use to discuss export trade. The chief sign affecting future trade is the gradual approach, in number of cases. of rates of exchange to the normal. The movements towards a more normal level are not uninterrupted, but for some time past the tendency has been in that direction. As an instance may be quoted the value of the French franc. A year ago the London exchange on Paris was about francs to the £, but it has gradually fallen, with a number of interim fluctuations, until it is now varying between 45.65 and 47.25. Apart from European countries, this tendency has been shown in the U. S. A.—although jut recently this exchange has again moved

from normal—Argentina, Japan and several other countries, where improvements have been shown since the beginning of the year.

Exchange difficulties have been one of the chief hindrances facing export trade, and improved conditions in this respect are looked upon as a very hopeful factor.

PRICE REDUCTIONS REASONS FOR THE DROP

The Bethlehem Steel Co., South Bethlehem, Pa., made an important reduction in steel prices recently. The table below shows the old and new figures:

	Old Prices	New Prices
Bars	2.10	1.90
Structural Shapes	2.20	2.00
Plates	2.20	2.00
Sheet Bar	39.00	35.00
Billets, 4 x 4	37.00	33.00
Slabs	38.00	34.00
Blue Annealed Sheets	2.85	2.65
Black Sheets	3.75	3.50
Galvanized Sheets	4.75	4.50
Tin Plate	6.25	5.75
Skelp	2.20	2.00

These new prices represent a reduction of $4.00 per ton on bars, structural shapes, plates, skelp, billets, sheet bar, slabs and blue annealed sheets; $5.00 per ton on black and gavanized sheets; $10.00 per ton on tin plate.

According to a report issued by the company the present manufacturing costs do not in any sense warrant these reductions, but it is stated that they hope this action will help to bring the market to a normal basis. They state that the increase in freight rates has been the largest factor in increasing the cost of manufacturing steel products because the making of a ton of finished steel involves the transportation of more than 5 tons of raw materials. The cost factors next in importance are materials and labor.

Taking as an example the price for structural shapes, under the new schedule prices, 2c a pound or $44.80 a gross ton, the comparison with pre-war prices, reflecting concretely the three more important cost factors are as follows:—

1. The increase over pre-war cost in transportation on ore, coal, limestone, scrap and miscellaneous supplies amounts to $7.85 per ton of finished steel. 2. The increase in the cost of coal, ore, limestone, alloys, refractories, lubricants, and miscellaneous supplies at point of shipment amounts to $7.10 per ton of finished steel. 3. The incretse in the cost of labor under the present wage scale, as compared with pre-war wages, in the steel plant proper, is $5.64 per ton of finished steel.

These items account for an increase in present day costs over pre-war costs of $20.59 per ton of finished product. The new price of $44.80 for structural steel is equivalent to a pre-war price of $24.21 per ton, or 1.08c per pound. Statistics covering the last twenty years show in only one month (December, 1914) has structural material been sold as low as this figure (1.08c). The ten-year pre-war average (1904-1913) was 1.51c per pound. The figures used are the results of actual compilation made by the company's comptroller in the every day conduct of the business.

EXPANSION REAMER.

The New Britain Tool & Mfg. Co., New Britain, Conn., have placed on the market a six blade expansion reamer that is said to be adapted for use in machine shops and garages. The ends of the blades are ground in such a manner as to serve as a pilot, and the range in sizes is from 15/32 in. to 4 1/16 inches.

TRADE GOSSIP

Work on the new St. Clair river channel is now nearing completion, and will soon be ready to accommodate the Great Lake freighters. Inspectors have stated that only a few lumps remain in the channel bed, and these are being removed by the dredge. Heretofore all large ships have had to use the same channel on the Sarnia side, a number of serious collisions having taken place as a result. When the new channel is ready, which it is expected it will be within the next two weeks, upbound steamers will take the Sarnia side and down-lake boats will pass on the other side.

Henry Ford seems to be at it again. This time he is said to be after the great nitrate plant at Muscle Shoals, Alabama. Reports claim that he has offered the Federal Government $5,000,000 in cash, and a yearly lease of $1,500,000 for its rental. As far as is known, it is his intention to manufacture commercial fertilizer, to be used in connection with his Ford farm tractor industry.

The investment house of H. L. Coombs Co., Ltd., who have a representative in Three Rivers, announce that they have added three new depts. to their busines, viz., pulp and paper machinery equipment, pulp and paper products, also an engineering and contracting dept.

Mr. L. H. Jenssen will have charge of the latter dept., and he has had a varied experience in different parts of the world on such work as railroad construction, bridge building, and concrete work.

TRADE GOSSIP

The Diamond State Fibre Company Canada, Limited, will be represented the Canadian National Exhibition be held in Toronto during the two eks beginning August 27th. The Exbit will be in the Industrial Building. e different grades of raw material ll be shown as well as the finished oduct in the shape of noiseless waterof gears, machined parts for elecal use, receptacles, automotive parts, There will also be exhibits of arles in which Diamond Fibre has been ilized for machined parts in the place wood, metal, rubber and other subnces.

Representatives of the Company will at hand every day to thoroughly exin its uses to anybody interested.

The Canadian Chicago Bridge and n Company, Limited, of Bridgeburg, tario, and Montreal, Quebec, has nged its corporate name to Horton el Works, Limited, according to an nouncement made by C. H. Scheman, neral manager of the company. The nadian organization was first incorated in 1913 and the plant at Bridgeg, Ontario, was constructed in that r.

Mr. Horton is said to have been one the pioneer engineers of North erica. Starting with a timber bridge Orinoco, Minnesota, in 1865, he deoped a large business in the design, fabrication and erection of bridges, el tanks, etc. In the early nineties, revolutionized the steel tank busins by inventing the hemisphericalbottom elevated steel tank of which usands are now in use throughout world. A few years ago his son, George T. Horton, now president of Horton Steel Works, Limited, inoted the elliptical bottom tank with ted steel riser which was a further ance in the art of steel tank buildn Mr. Scheman and Mr. G. S. Sangill will be located at Montreal, while C. C. Gregory is manager of the t. Mr. F. E. Gregory will be superndent of erection.

e Westinghouse Electric & Mfg. Co. nounces a ten per cent. reduction on s of practically all of industrial ors and motor control apparatus, inhing also all direct current generrs and motor generators. This is the nd cut of ten per cent. made by company in motor prices during this r. There is also a reduction in prices n eating appliances, such as toaster s, irons, chafing dishes, cozy glow ors, etc. The new prices to take effect immediately.

S. V. McLeod has been appointed purchasing agent for the Algoma Steel Corporation, Ltd., with headquarters at Sault Ste. Marie, Ont.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

AMERICAN STEEL SPLIT PULLEYS

More than five million "American" Pulleys now save power in efficient shops here and abroad.

Basic Principles that Stand New Tests

SUCH features as strength, durability, weight, power conservation and ease of application of various types of pulleys were tested and studied in designing the "American" Pulley. Though there have been refinements, it is significant that the basic design has met every new test.

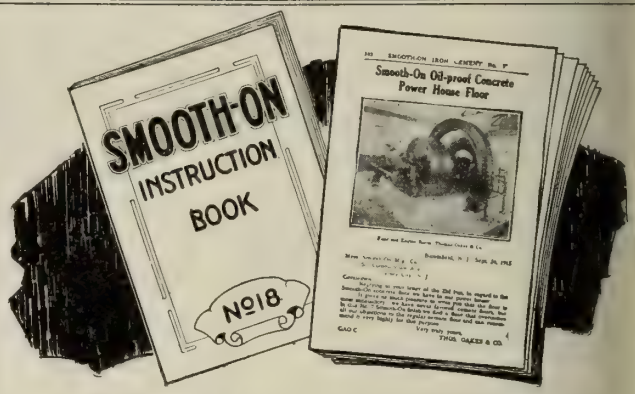
Send for booklet, "Getting Maximum Pulley Efficiency," which shows commonly unknown pulley facts.

The American Pulley Company
Philadelphia, Pa.

The AMERICAN PULLEY
A wheel with a broad rim transmitting power from or transmitting power to machinery, or changing the direction of motion by means of a flat belt.

Grey Iron and Semi-Steel Castings

Any Weight up to 75 Tons



Special Equipment for Heavy Machining.
including
Boring and Turning Mill to swing 35 ft. diam.

Heavy hydraulic work a specialty.

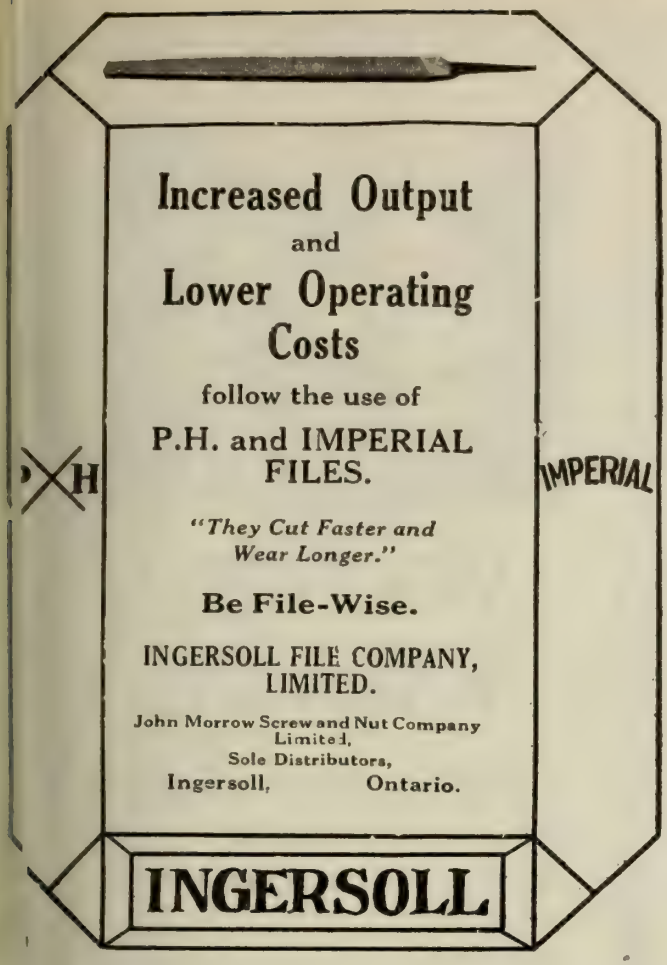
A 144 PAGE BOOK---FREE



Written *by* and *for* Engineers

This latest edition has been completely revised—new material inserted, new repair problems described.

The Smooth-On Instruction Book No. 18 is the most valuable book of its kind. Its 144 pages contain sound practical and money-saving advice on various power plant and boiler room repairs. Its compilation has been contributed to by engineers the country over.

Your copy is waiting—all we want is a word from you and we will send it along.

WHAT IS YOUR ADVERTISING DOLLAR BUYING?

High prices of materials and increased overhead have made necessary a stricter economy along mercantile lines.

Advertising should be considered as well as the commodities in which merchants deal.

By choosing only those publications whose circulation is accurately measured, you not only practise economy in your advertising, but are assured that your money is buying a definite quantity of circulation.

The **CANADIAN MACHINERY'S** circulation is measured by the Audit Bureau of Circulations. Advertising placed in its columns is an economical investment.

GARLOCK-WALKER LIST

Over 20,000 square feet in our warehouse is filled with every variety of Equipment for Machine Shops and Woodworking Factories.

You will find Garlock-Walker service thoroughly dependable. Let us know what Machinery you require.

If you want Machinery Equipment, send us your enquiries.

A few Machines from our Toronto stock at exceptionally attractive prices are:—

LATHES

1—144" x 12' Berg Pit Lathe (used).
1—36" x 18' Putnam (used).
1—30" x 12' Blaisdell (used).
1—30" x 14' Niles-Bement-Pond (used).
1—26" x 14' Niles-Bement-Pond (used).
1—24" x 10' Milwaukee (new).
1—20" x 6' Le Blond Heavy Production (used).
1—18" x 8' Bertram (rebuilt).
1—18" x 8' Rae (new).
1—16" x 6' Reed (used).
1—12" x 8' LeBlond (used).
1—8" Rivett, Bench, Cabinet and Attachments (used).
1—7" Cataract Precision, Standard Equipment.

GAP LATHES

1—22" x 40" x 16' McDougall (used).
1—20" x 38" x 12' C. M. C. (used).
1—18" x 24" x 10' Rahn Meyer (used).

TURRET LATHES & SCREW MACHINES

Several No. 4 Millhollands. Davis, Oliver, Garvin, Warner & Swasey, and National Acme.

SHAPERS

1—16" Rae B. G. Crank Shaper (new).
1—24" McGregor-Gourlay Crank Shaper (used).

PLANERS

1—42" x 42" x 20' Putnam, 1 Head (used).
1—48" x 48" x 14' Patch, 4 Heads.
1—36" x 36" x 24' Sellers, Open Side (3 Heads).
1—30" x 30" x 10' Pond, 1 Head.

MILLING MACHINES

1—Briggs High Duty Type "A", 22" Traverse (new).
1—Briggs High Duty Type "B" 42" Traverse (new).
1—Ryerson-Owen No. 3, Universal (new).
1—Ford-Smith, No. 3 Universal (used).
Several Plain and Small Hand Millers.

DRILLS

1—10" Burke Sensitive Bench (new).
1—15" Rockford (used).
1—16" No. 2B Edlund H. S. Sensitive (new).
20" "Sibley," "Champions," "Rockwell" and "Silver" (new and used).

BORING MILLS

1—Universal No. 2½ Horizontal, Table 42" x 22" (used).
1—Bullard "New Era" Type Vertical Turret, 36", Complete Equipment (new).

POWER HACK SAWS

1—No. 10 Racine 8" x 8" Cap. (new).
1—No. 7 Watkins, 9" Cap. (used).
1—No. 1 Racine, 6" x 6" Cap. (used).

GRINDING MACHINES

1—Landis No. 4 Universal (used).
1—Landis Plain, self-contained, 36" x 12" (used).
1—Fitchburg Cylindrical, 8" x 36" (new).
Tool and Cutter Grinders. New and used. "Globe," Stevens, LeBlond and Cincinnati.

AIR COMPRESSORS

1—8" x 8" Sullivan, Class W.G.-3, belt driven (used).
1—8" x 10" x 8" Bury, steam driven (used).
1—12" x 18" Ingersoll-Sargent, belt drive (used).
1—12" x 12" Can. Ingersoll-Rand, N.-E.-1 (used).

PRESSES

1—No. 0 Consolidated Inclinable Power Press (used).

MISCELLANEOUS

2—No. 4 Jno. Hall Pipe Machines (1 used), (1 new).
1—No. 4 Jno. Hall Nipple Machine (used).
1—Lennox Rotary Bevel Shear, 1" cap. (new).
1—6" Curtis Pipe Machine (used).
1—Beaudry Champion Power Hammer, No. 9 (used).
1—Grant Rivet Spinning Machine, No. 80A (new).
1—Grant Rivet Spinning Machine, No. 80B (used).
1—Greenerd Arbor Press No. 4 (used).
Transmission Equipment, Pulleys, Belting, Shafting and Hangers.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

A New Machine For Repair Shops

THE LANDIS No. 5 CYLINDER GRINDING MACHINE

The insistant demand for a machine to meet requirements of automobile cylinders re-grind resulted in the designing and manufacturing of new type grinding machine.

The machine will handle cylinders rapidly accurately and has a capacity great enough to inc all makes aud types of motor blocks, cast singly or ***en bloc.*** A centering vice, the exclusive feature, properly locates the cylinder holes with cent wheel rotation. Vertical adjustment is eliminated which permits a q set-up.

Together with other important features, this machine is ideal for shop.

Write for circulars.

If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.

Replacement Ends Replacement

Asphalt—The asphalt compound is used for the first coating because scientific experiments over a long period of years have demonstrated that it forms the best protector of steel against corrosion.

Asbestos—Asbestos felt also completely covers the steel and is firmly bonded to the asphalt. Because of its fibrous-crystal formation asbestos is indestructible. It cannot rot or decay. Acids and alkalies do not affect it.

Waterproofing—The third coating is a tough envelope of weather resisting and chemically inert compound. It forms the first protective layer which enhances and multiplies the durability of the finished product.

When you replace the old crumbling and costly corrugated sheets on your roofs and siding with Robertson Process Metal, you end replacement and repair costs for the longest possible period.

You are replacing with permanency. You stop painting expense. You reduce heating expense and you give your employees greater comfort in summer.

Plant operations need not be interrupted because of the ease, speed and freedom from ordinary construction confusion, with which Robertson Process Metal can be erected.

Robertson Process Metal is a substantial building material which has its steel core so fully protected that weather and such corrosive elements as smoke, gases, chemical fumes, etc., cannot touch it. The steel is hermetically sealed. Both surfaces and edges are completely encased with three impervious coatings. (1) Asphalt (2) Asbestos (3) Waterproofing. The process is sure protection. Powerful machinery presses and securely bonds these coatings to the steel. The small illustration opposite, below, shows how one layer follows another in the process of protection. Examination of an actual sample of R. P. M., however, will be still more convincing. Write today for descriptive literature.

KEMPSMITH

No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-story frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request

P & W

Pratt & Whitney Taps

"With the 'Con-eccentric' Land"

P & W Taps are **Good** taps—easily the best where accuracy and high speed are essential. They cost more to buy, but less to use than others.

If you're doing work that calls for big production and for unusual precision, give them a trial. You'll be back for more when you see them prove themselves.

The "con-eccentric" land — the special feature of Pratt & Whitney Taps, permits sharpening on face of the cutting edge without affecting size. It lengthens life and assures accuracy hitherto thought impossible in a commercial tool.

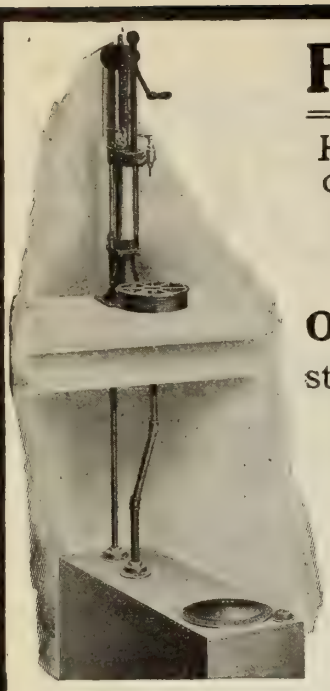
Torrington

MACHINE SCREWS

Something You Get Without Paying for

You're way ahead---in fact money in pocket---when you specify Torrington Machine Screws because the same price asked anywhere else for ordinary Machine Screws when invested in Torrington buys you additional, "free gratis" value.

You obtain Machine Screws that are made by high-salaried, thoroughly-experienced workmen—you do not pay for the practice work of beginners. *Yet this guarantee of uniform quality costs you nothing extra.*



You have a wide choice of STANDARD SCREWS to choose from (standardization enables the user to provide correct style and make of taps) and the most complete facilities available for the manufacture of SPECIALTIES. Yet this *costs you nothing additional.*

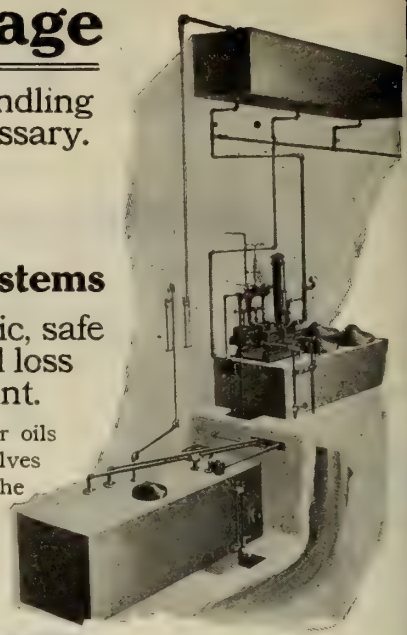
Are not these points worth investigating? The Torrington Line includes Standard and Special Machine Screws, Rivets, Threaded Wires and specialties in Headed Work.

A small representation of the many styles we make.

The Torrington Company, Limited.

Upper Bedford, Quebec.

Plan Your Oil Storage



Haphazard methods of storing and handling oils are costly, dangerous and unnecessary.

BOWSER ESTABLISHED 1885

Oil Storage and Distributing Systems

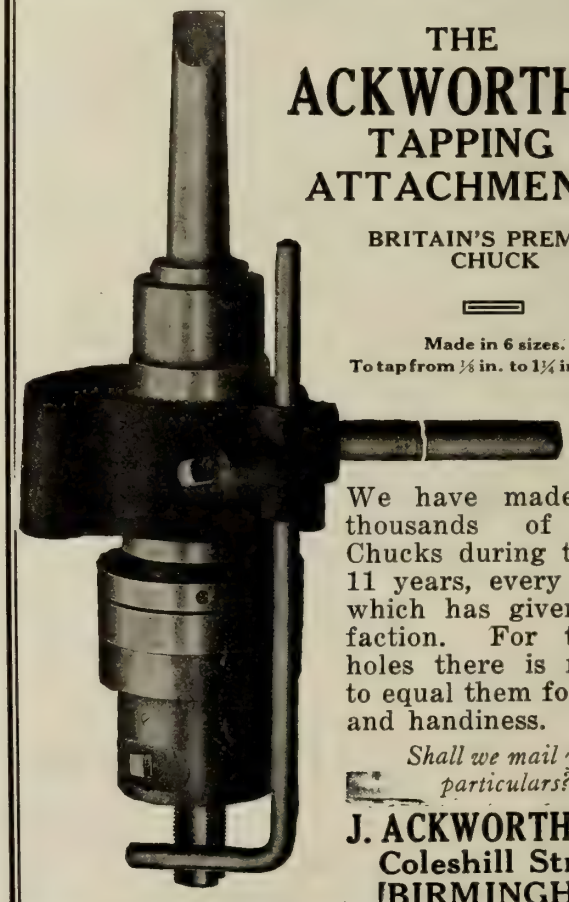
store and handle all oils in a systematic, safe and saving manner—they prevent all loss of oils—make every drop of oil count.

In factory, machine shop, power plant or wherever oils are used, BOWSER Storage Systems pay for themselves many times, through the saving in oils, besides the saving in labor and floor space.

S. F. Bowser Co., Ltd.

66-68 Fraser Ave., Toronto, Can.

BOWSER Oil Storage GIVES Convenience AND Safety



BOWSER Oil Storage IS Systematic AND Saving

How to Plant an Advertising Crop

Until the advent of the Audit Bureau of Circulations, advertisers sowed their business seed in a vast but fallow field. Some of it grew and returned a fair harvest—much of it was cast upon barren ground and was lost. There was no standardized method of determining the fertility of a publication's field. Experimenting was expensive.

The A. B. C. has eliminated the barren spots of circulation. Planting an advertising crop is no longer an experiment. Advertisers **Know** the field through audit reports. They know whether it is fertile ground and sow their seed accordingly.

The Canadian Machinery circulation has been audited by the A. B. C. Advertisments placed in this publication are seeds well sown.

THE
ACKWORTHIE TAPPING ATTACHMENT.

BRITAIN'S PREMIER CHUCK

Made in 6 sizes.
To tap from ⅛ in. to 1¼ in. Whit.

We have made some thousands of these Chucks during the last 11 years, every one of which has given satisfaction. For tapping holes there is nothing to equal them for speed and handiness.

Shall we mail you particulars?

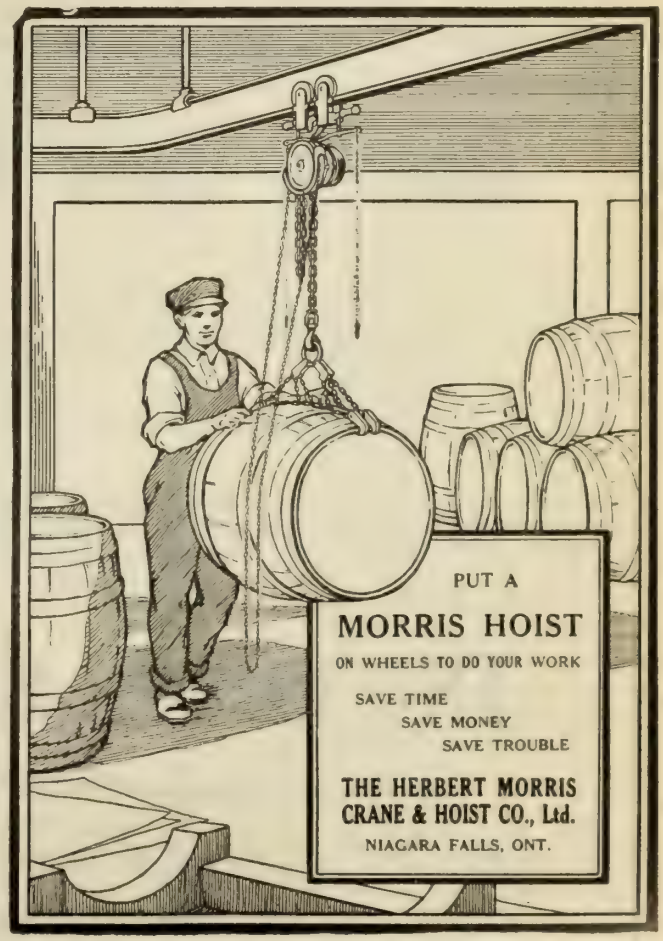
1/3 to 1/2 Reduction in Milling Cost

This will be the result of taking small milling jobs from your big millers and putting them up to



The U.S. MILLER

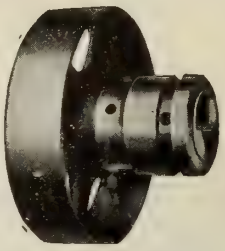
The Miller for Small Work

A small machine takes up less space, requires less power, is easier to operate and is more accurate.

The Paramount Miller of its size. Drop us a line for full details.

United States Machine Tool Company
Cincinnati, Ohio, U.S.A.

THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

FORD-SMITH

DISC

Grinders

High-Class Made-in-Canada Machines

MACHINES which bear a reputation for doing quicker, better work, and whose upkeep expenses are practically nil, merit investigation.

Such machines are Ford-Smith Disc Grinders; every model of the Ford-Smith line—and there's a model for practically every purpose—is designed to give quality production as well as quantity.

Before leaving the factory all Ford-Smith Grinding Machines are subjected to a series of exacting tests, covering every detail of their construction. These tests prove that the machine is capable of filling all our claims.

Many manufacturing operations show possibilities of exceptional economies by the use of suitable grinding processe. Have one of our engineers call and see just what saving grinders would effect on your work.

Any information with regard to Ford-Smith Grinders will gladly be furnished.

Send for our latest Disc Grinder Bulletin.

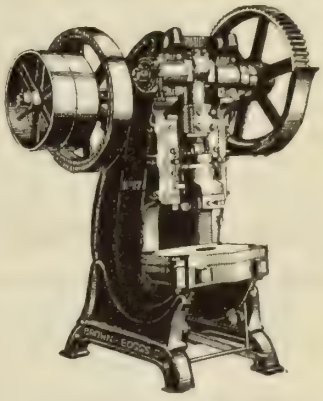
BROWN-BOGGS

B B

Builders of Volume Production



No. 15--Power Press

The "B-B" line consists of machines and tools for sheet metal, tinsmiths' tools and machine dies, shears and punches of every description.

Almost every present day manufacturer is looking for the same thing—a machine capable of turning out more top-notch quality work in a day than has ever been produced before. In this way—and in this way only—can present industrial conditions be met with profit.

You realize this fact. We realize it. That's why we earnestly urge you to investigate the sturdy quality and production ability of *B.B. Power Presses.*

Canadian Machinists and Metal Workers have, in the past, been well acquainted with the B.B. stamp of never-failing service. To-day it stands forth conspicuously as the mark of thorough workmanship — through and through.

No. 17--Power Press

A complete line of canners' processing machinery; evaporating machines, special machines. and power presses for punching, forming, embossing, blanking, etc.

Let us know the machine you are interested in and complete information will be promptly supplied. If you wish advice consult us freely.

"ROYLITE" CLEANER

Cleans All Metals

Made In Canada

Oil, Grease, Paint, Varnish, Enamal

All Quickly Disappear before "ROYLITE"

Ask any man who has ever used "Roylite" Cleaner, why he prefers it and this is what he'll tell you. "Roylite" is the fastest, most effective cleaner we have ever used. It lasts longer and costs less than any other.

Here's the reason "Roylite" is different to most cleaners. It emulsifies or lifts grease from the work and does not lose its strength in saponification like Caustic Soda, Lye, Soda Ash, etc., by creating a soap in the solution. This enables the use of both with less additions of this cleaner than others.

"Roylite" is easy to apply. All chemicals are soluble, quickly dissolve in water, and are ready for immediate use, "Roylite" is guaranteed not to discolor or tarnish the brightest surface.

Would You Like to make some Extra Money?

Of course you would. Well then, why not do so? Canadian Machinery is always on the lookout for well-worth-while ideas, and are willing to pay a good price for them.

We are often asked, "What sort of ideas do you want?" Briefly, what we are desirous of obtaining is this, "Any idea that has proved of value in the machine shop, drafting room, or tool room." Think of how you got over some difficulty, a ticklish piece to hold in the lathe, or perhaps how you increased production on some particular piece. Any idea that saves time or money in the machine industry will appeal to us. Never mind the style. Write it as best you know how. We will put the finishing touches to both the wording and the sketch. Start in **NOW** and send us something of such a nature.

Address it to

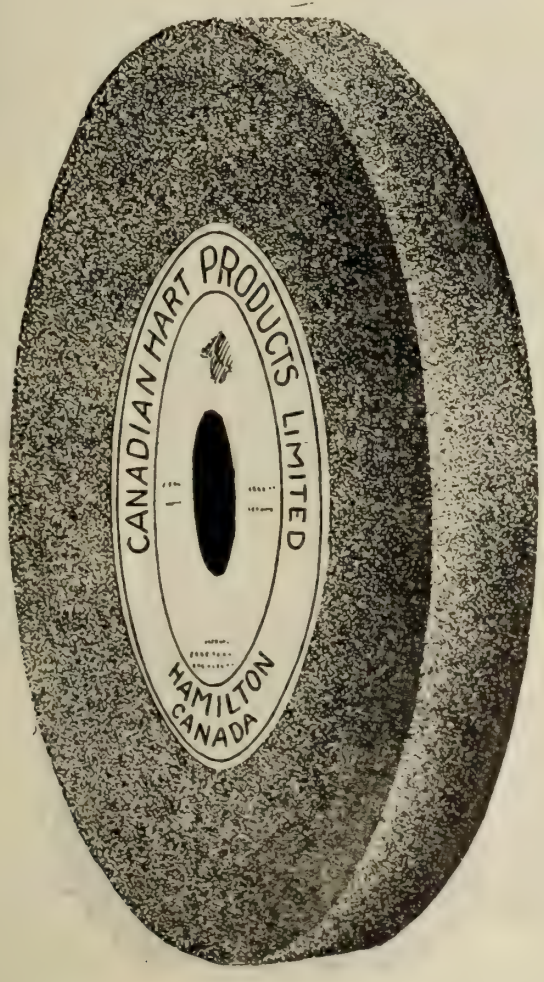
Heading and Forging Machines

Canadian Hart Wheels

Dependable wheels — correct in grade and grain— for every class of grinding work.

Don't choose the wrong wheel. You'll waste time and money. Specify HART. Hart Wheels are uniform. Tell us the class of work and we'll tell you the right wheel to use.



Vitrified
Grinding Wheels

These wheels are the most generally used and give the greatest satisfaction for the majority of grinding jobs, since the bond is less affected by heat and may be used wet or dry. It takes from 20 to 30 days to manufacture a wheel by this process.

Silicate
Grinding Wheels

Silicate Wheels may be manufactured in 24 hours. These wheels derive their name from the large portion of silicate contained in the bond. We manufacture Silicate wheels with or without web as specified by the customer.

Open Hearth Steel
U. S. S. Threads.

On this particular Landis Threading Machine 700 studs were being threaded on both ends in 9 hours. This is a total of 1,400 threading operations in that time. The foreman tells us that neither the operator nor the machine were going anywhere near the limit, and also commented on the endurance of the dies, which are "so much longer lived than other dies that there is no comparison."

He summed up the performance of this Landis Threading Machine and Landis Die Head in the following words: "Absolutely O.K., the best threader in the world."

Production "Cost Cutters"

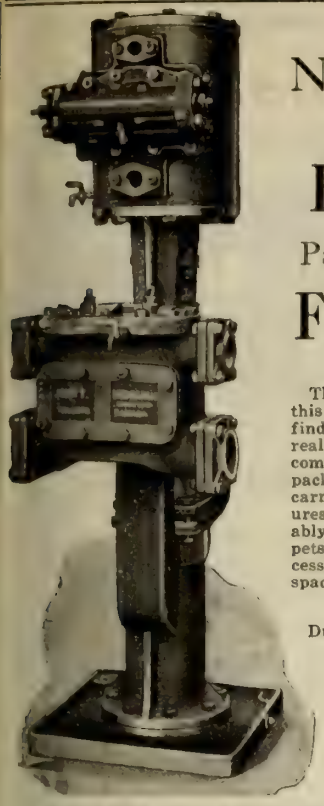
Specify "Barnes-made" Spring Washers and Stampings, and reduce your cost of production !

In our Stampings Department we have a multitude of special tools and special automatic machines, all "Barnes-made" and designed for cutting washers and stampings . That's why we can save you money.

We make these parts of cold-rolled steel, tempered steel, brass, bronze, copper, German silver—or any required material—according to your needs.

This work is done with the exact same care, skill and accuracy we employ in our spring making. It merits the confidence of manufacturers of even the most delicate and intricate mechanical devices.

Catalogue No. 9 is worth asking for May we send it ?



Springs of steel, brass, phosphor bronze or vanadium —flat, coil, spiral, —compression, extension or torsion. Wire Forming. Spring Washers. Small parts of steel, brass, etc., in any finish. Assemblies. High Carbon Cold - Rolled Steel.

NO EXCUSES

With the

HEPBURN

Patent Vertical Ram

FEED PUMP

There are no excuses attached to this Hepburn Patent Pump. You'll find that out if you give it some real work to do. It is a sturdy, compactly constructed, outside packed type for Feeding Boilers carrying the highest steam pressures. The construction is remarkably simple and eliminates all tappets and levers. Every part is accessible, and it takes little floor space in the Power House.

Duplex Pumps, Vertical Engines, Compressors, Hand and Electric Overhead Cranes for Power House Service are also products of the Hepburn plant.

THE CANADA METAL CO., LIMITED

TORONTO HAMILTON MONTREAL WINNIPEG VANCOUVER

Asbestos Fibre (Liquid) Cement

—a rubber-like adhesive and tough preparation made from finest asbestos fibre, creosote and durable oils. Makes any roof, no matter in what condition, absolutely proof against climatic conditions. Easily applied over any kind of roof; metal, gravel, paper or composition.

Jewel Roofing

Comes in 1, 2 and 3-ply, guaranteed respectively for 3,5 and 8 years. We think it is the best value on the market for this quality of roofing.

Hexagon Slab Shingle

Hexagon Slab Shingle is durable; it will give years of consistent roof service without repair costs. It is fire-resisting, too.

The hexagonal figures present a distinctive and attractive surface. The patented design produces a beautiful shadowed effect that adds to the pleasing appearance of the roof.

Excello Roofing

In 1, 2 and 3-ply, guaranteed for 5,10 and 15 years respectively. Place your orders early.

English Millboard

We have a large stock of the finest Grey English Millboard ready for immediate shipment. The high quality of this board is very well known. If you have not already seen it, we shall be glad to send you samples.

We can supply the millboard in three thicknesses—3-16″, ¼″ and 5-16″. Shall we quote you prices?

Asbestos Sheathing

There is a constantly growing tendency to consider fireproof buildings as a necessity. Asbestos Sheathing is a recognized fire-prevention material.

We also carry a full stock of regular lines of plain and tarred felt in 10, 12 and 16-oz. eights.

RICE LEWIS & SON, LIMITED

Established 1847 TORONTO, ONT. 19 Victoria Street

"Hisco" Machine—Molded Gears

The fact that "Hisco" Machine Molded Gears require no pattern is a factor of considerable importance when the price of lumber and labor is so high. "Hisco" quality insures accurate, dependable gears. Remember — **the price of "Hisco" gears does not include the cost of patterns.**

We are also manufacturers of Steel, Chrome, Manganese and Nickel Steel Castings, Annealed and Unannealed; Cement Mill and Mining Machinery; Castings; Stamp Mills; Crushing Plants; Excavating Outfits; Steel Car Wheels; Locomotive Driving Wheels and Frames, etc.

Let us know your requirements—we do the rest.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force cannot replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every month will keep you posted on the latest developments for machinery equipment.

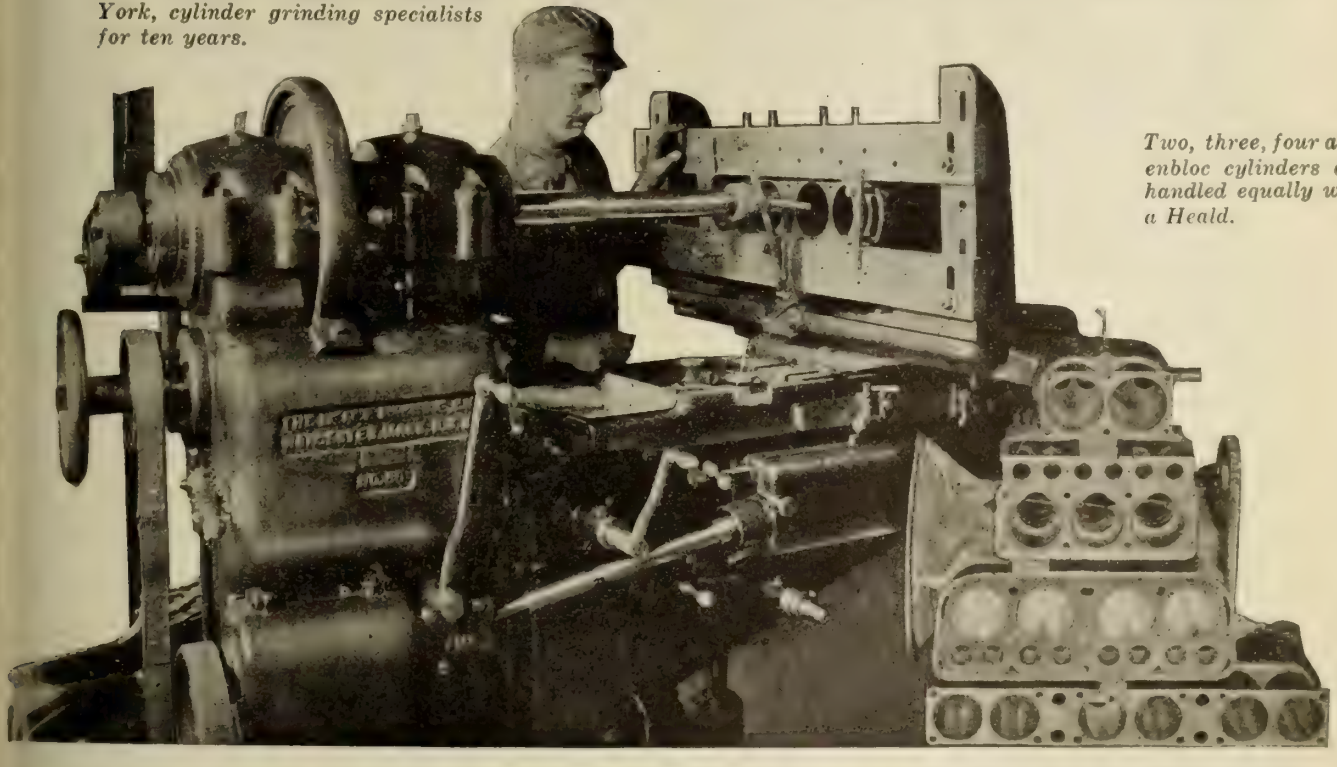
It's Safe to Follow a Good Lead

"Cylinder Grinding is Our Business—that's why we use Healds"

HEALD

Cylinder Grinders

That's the statement of Joseph Buckley, Shop Superintendent of the P. J. Durham Company, Inc., New York City. This Company has been in business for ten years, during which time it has always used Heald Machines. Mr. Buckley says he knows of no other grinder or method which will give as satisfactory and economical job.



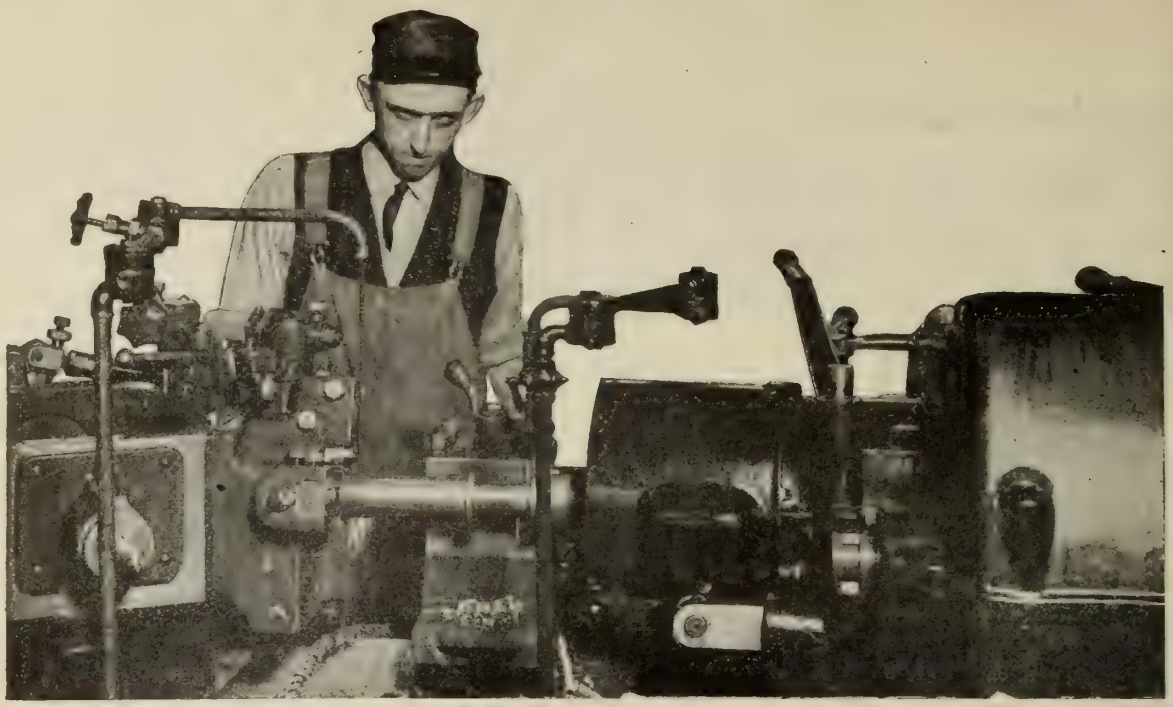
Mr. Buckley is right, and his statement is backed up by over 500 other concerns using Healds in the United States for this work.

In Canada there are 402,929 registered cars with only 12 concerns Heald-equipped to do this work. Can't you see the opportunity when three four-enbloc cylinders a day will bring handsome returns to a two-man shop? There are many localities without a single shop suitable for regrinding, and further, remember that the first to start gets the cream of the trade.

It is high grade work, pays big profits on the investment and does not require skilled workmen for operators.

We would like to get in touch with you personally or by mail. Write today while you need the business.

Regrinding a Saxon block at the P. J. Durham Company, Inc., New York, cylinder grinding specialists for ten years.



Two, three, four and six enbloc cylinders are all handled equally well on a Heald.

To Decrease Operating Costs

The side carriage is an important part of the W. & S. turret lathe. It reduces operating costs, often by as much as one-half. It operates simultaneously with the turret and independently of it. The side carriage has a separate feed rod.

Take some of the simplest bar jobs; by cutting off with the side carriage while the turret tools are finishing their work, you save most of the cutting off time.

Here is the picture of a W. & S. 2-A. in a railroad shop. This machine makes bolts, pins, oil cups, valve parts, piston rods, and many other parts used in the repair of locomotives and cars.

On all these parts both turrets operate together.

Take this feature and the fact that the machine operates easily and accurately, and you know why the machine is popular with the shop men. It delivers the goods.

Send us blue prints of your parts and we'll tell you how long it will take to do your work the W. & S. Way.

Williams' Drop-Forged Hammers Are Superior

BECAUSE:

1. **The heads are drop-forged from a fine, specially selected grade of high carbon steel.**
2. **They are heat-treated and carefully hardened and tempered so that they will not chip, or wear unevenly.**
3. **Special steel wedges are used to secure the head to the handle —they cannot work loose.**
4. **The handles are made of the best grade of selected, straight grain, white hickory—wax finish.**
5. **Each tool is properly balanced, insuring a powerful stroke, with the least effort.**

Like all Williams' specialties, these hammers are the result of years of constant effort to produce superior tools. They are correctly designed and made to do their work with ease and satisfaction to the user. There are none better.
All patterns and sizes. Catalog on request.

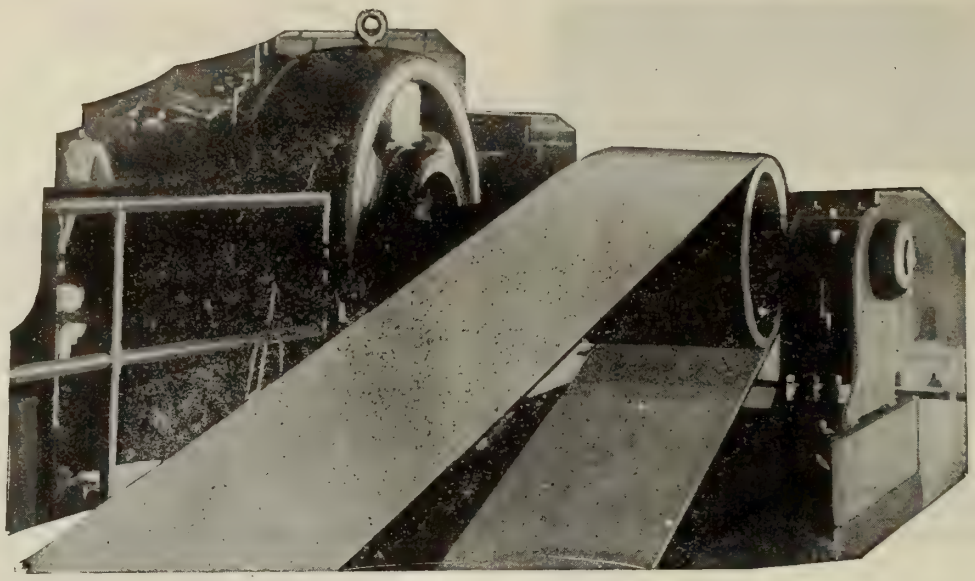
Franklin Die Castings for Domestic Devices

Spreading a Great Educational Influence.

NOT so long ago good music was a treasure of the chosen few. Years of study were necessary to play an instrument. Today, irrespective of technical skill, the great educational influence of good music is at the command of everyone. Among other modern manufacturing methods the Die-Casting Process has been instrumental in enabling the general public to enjoy good music. Franklin Die-Castings, used in phonographs, player pianos and organs, have helped to reduce production costs in the manufacture of these instruments.



Franklin engineers, in 1892, originated the die-casting process. Franklin Die-Castings have helped manufacturers ever since to speed and simplify production in many fields of industry.

The addition of the standard No. 12 Aluminum to the Tin, Lead and Zinc base alloys already in use enables us to meet a still wider range of individual needs.

We quote from samples or blueprints. Write for booklet "Franklin Die Castings in Many Fields."

The Most Belting Service For Each Dollar Invested

Dominion Friction Surface Belting properly installed, means greater power economy because its flexibility makes it suitable for use on cross curves and where idlers are encountered. Its greater strength and pulley gripping power make it the most dependable for main drives, countershafts, large motors and heavy machinery where the belts are large.

Dominion Friction Surface Belting meets the diversity of conditions encountered in all industries. The Dominion Rubber System stakes its reputation on the unqualified success of Dominion Friction Surface Belting.
Our belting engineers, without cost to you, will study conditions in your plant and submit recommendations for your approval. Phone or wire our nearest Service Branch.

Why should I buy GTD Taps and Dies?

AS you turn the pages of the magazines and note the many advertising announcements—you must often have asked this question:

"Are all taps and dies alike?"

If they are, then your decision is influenced mainly by the attitude of the people who make them—their friendliness, their understanding of your needs, and their aggressiveness in urging you to buy their product instead of some other.

If taps and dies are *not* alike, how do they differ?

Take the matter of metal buying—or heat treatment, or uniformity in production. Some products excel over others in each case. Or consider accuracy, rapidly becoming a first consideration in buying taps and dies. Or such elements as adaptibility or application!

Consider GTD with these fundamental differences in mind. Think of the tap and die specialties now so universally used which are ours and were first made by us:

The Button Die
The Round Adjustable Split Die
The *"Little Giant"* Die
The *"Acorn"* Die
The *"Gun"* Tap
The *"Maxi-Staybolt"* Tap, etc.,

In all of these tools there are *differences* which distinguish them from taps and dies so often thought of as "all alike."

Back of these differences is the pioneer work in screw-cutting tool manufacture, of Wiley & Russell, Reese, Wells Brothers—names that have stood and still stand for the painstaking effort that only real genius gives to its task.

No, taps and dies are not all alike. There are differences that most observers can detect. And these differences which make it worth any tool-user's while to look for the GTD trademark and *insist on it*—are the things on which our advertising and our salesmanship put the emphasis.

Screw Thread Text Books Free

Our catalogs and descriptive booklets on GTD threading tools are really text books on the subjects they cover and as such are valuable to any shop worker or executive. Let us mail them to you without cost. Use the coupon and indicate whether you are using production or repair tools or both.

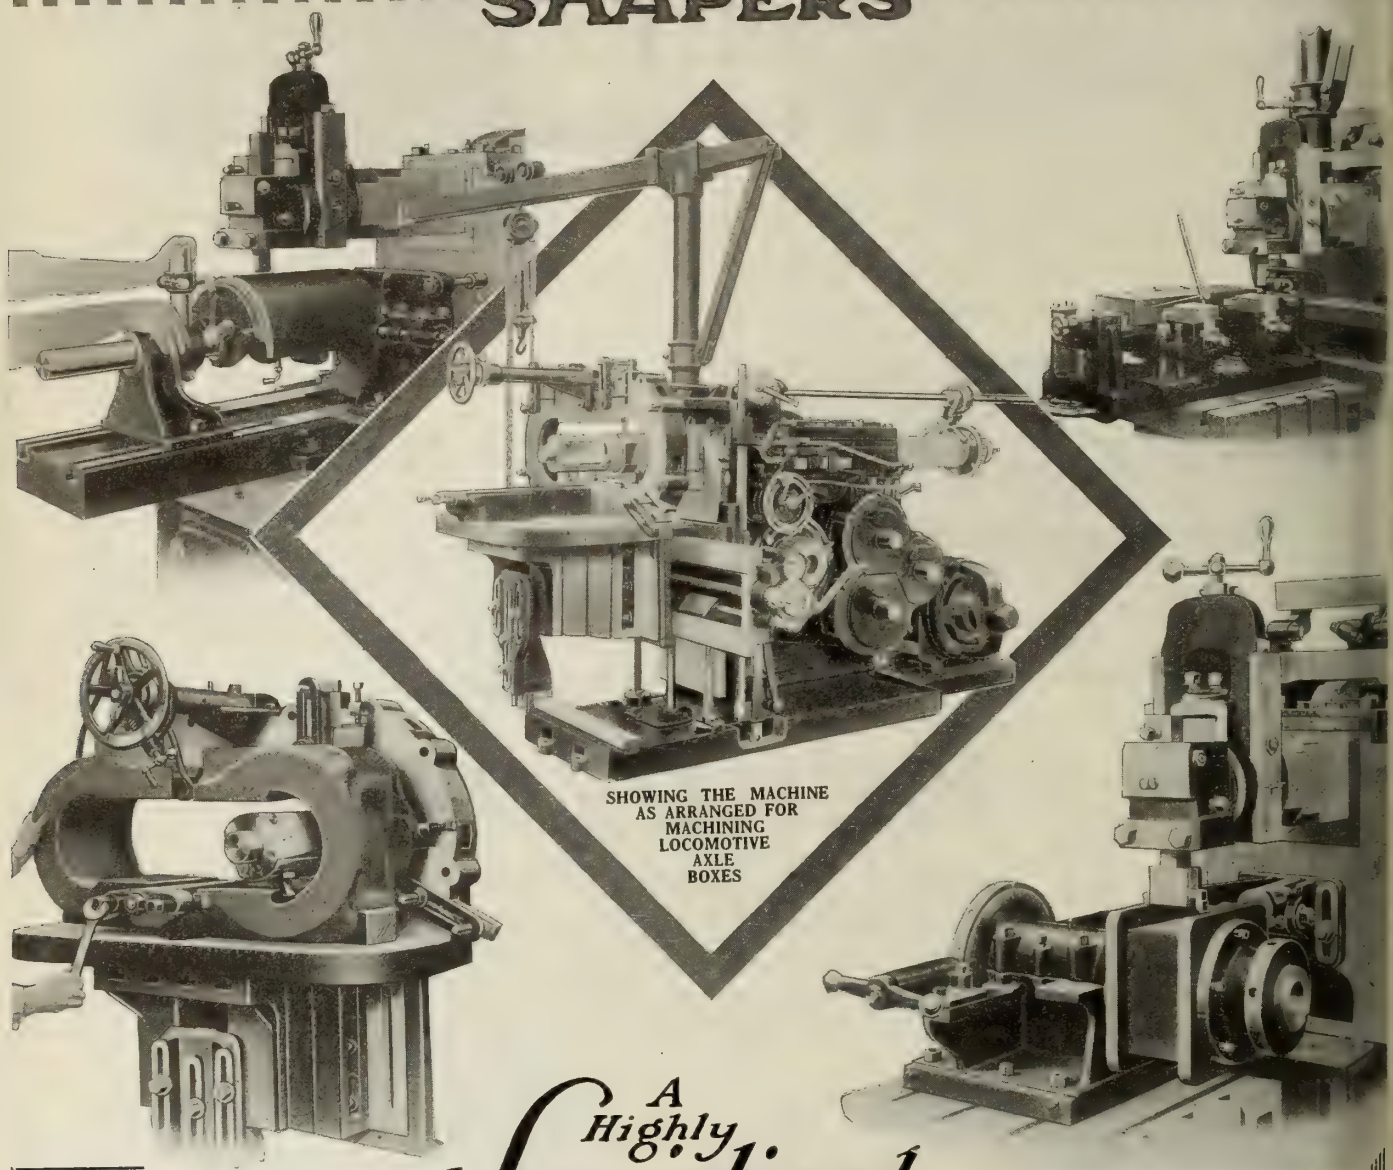
HENDEY

THERE is never any question of a Hendey's ability. Every lathe, shaper, miller and centering machine must pass a series of rigid, well rounded tests before it is passed for shipment. A complete test and inspection record is made for each machine. Thus, a customer knows just what results he can expect in the way of accurate turning, boring and facing from the machine he has purchased.



On the left the testing of the alignment of the cross slide travel with the spindle of a Hendey Lathe is shown. The straight-edge-tissue-paper test used shows in the majority of cases a perfectly flat plate after the same has been faced with tool. A slight variation is allowed, however, toward concave on the plate not exceeding .00075″.

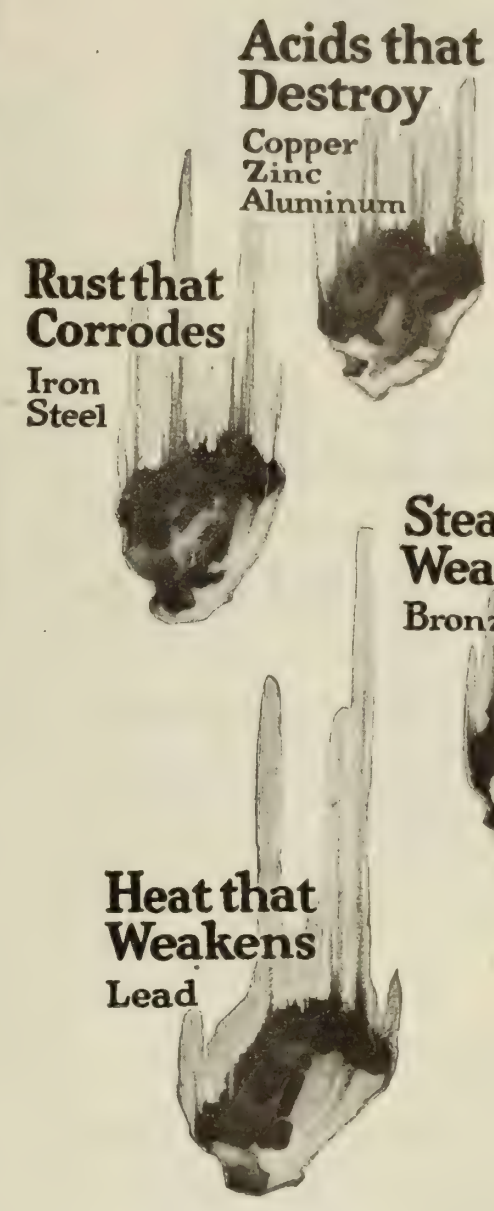
LATHES—MILLERS—SHAPERS AND CENTERING MACHINES

MORTON
HEAVY DUTY RAILROAD SHAPERS

SHOWING THE MACHINE AS ARRANGED FOR MACHINING LOCOMOTIVE AXLE BOXES

A Highly Specialized MULTI-DUTY MACHINE

THIS Morton Heavy-Duty Draw-Cut Railroad Shaper is a specialized tool of exceptional design.



It is a multi-duty machine and the ease and rapidity with which changes are made from one class of work to another are features which make it a highly profitable producer. Fully equipped with the latest time-saving devices! A machine of maximum rigidity! Deep cuts, coarse feeds, and smooth and accurate work make it a tool of outstanding ability.

Send for bulletin 6A—it contains a complete and interesting story of this finely built tool.

MORTON MANUFACTURING CO.
MUSKEGON HEIGHTS, MICHIGAN, U.S.A.

If interested tear out this page and place with letters to be answered.

Why are these metals discarded by many manufacturers?

THEIR life is too short for the service required of them. Manufacturers must use materials that survive. High heats, acid action, steam wear, salt pitting and rust take no toll from **MONEL** Metal. Strong as steel, more wear and corrosion resisting than copper or bronze, **MONEL** combines the best physical properties of other metals without their limitations

Do acids or other chemicals destroy your dairy, mining, refrigerating, bleaching, dyehouse, oil, sugar or like industrial machine parts? Does rust corrode your window screen; kitchen or laundry equipment; automobile or boat trim? Make them of **MONEL.**

These corrosive forces have no effect on **MONEL** Metal. Nor is **MONEL** weakened by heats that break down the structure of other metals. In the country's power plants, **MONEL** valve trim, turbine blading, cylinder liners, etc., are standing up against the continuous cutting wear of superheated steam and hot gases. No other available metal or alloy possesses such a wide range of usefulness.

The name MONEL identifies the natural nickel alloy—67% nickel, 28% copper and 5% other metals—produced by the International Nickel Company.

Quantity Production of Shafts in Automatic Heat Treatment Furnace.

PRODUCTION MANAGERS

The following advantages are secured by the Continuous Method of Heat-Treatment :

Increased production per unit of floor space.
Reduction in manual labor per unit of production.
Uniformity of product, resulting in decreased scrap, following less dependence upon the human element.
The fuel economy that naturally follows the direct transfer of heat in spent gases to incoming material.
Improvement in working conditions by cooler shop.

In short, the saving in cost of the finished product due to economy in labor, time, fuel, floor space, decreased rejections, etc.

Do these advantages appeal to YOU?

Write for Bulletin 217-T and learn whether this method is adapted to your product and manufacturing conditions.

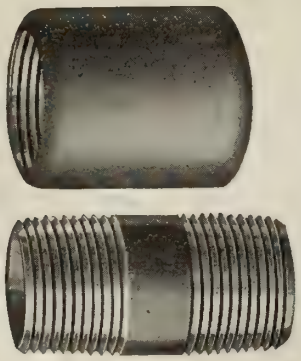
Correct Lighting in your Plant means More Work and Better Work

Let Us Ease the Eye Strain

Good lighting is a factor of first consideration in any effort to improve workmanship, increase production, reduce spoilage and safeguard employees.

A poorly lighted plant breeds weariness and discontent, resulting in uneven production and waste. Ease the strain and get more and better work from a happier staff by installing a correct Industrial Lighting System in your plant.



Our Illumination Engineers will gladly help in solving your particular lighting problem by planning the system that will most efficiently and economically meet your need. Such well-known names as Benjamin, Adams & Bagnall and Overbaugh and Ayres are included in our stocks of Illumination Equipment.

The Right Way to Heat Your Factory

Install a Skinner Bros. (Baetz Patent) Heating System and there will be no more hot or cold spots in your factory—it will be comfortably warm all over all of the time, regardless of weather conditions. This is the right method of factory heating.

Skinner Bros. (Baetz Patent) Heaters do away with complicated pipes or ducts, are portable and require no special foundations. As a result, installation cost is 15 to 50 per cent less than any other system, with equally low operating costs. The mild, gentle circulation of warmed air provided by this heater does not create drafts or establish other conditions injurious to the health and welfare of your employees. Satisfactory performance guaranteed on a money refund basis.

Type SC—Where Steam is Available

Consists of a series of steam coils compactly mounted in an enclosed case, above a powerful fan-wheel. Cold air at the floor level or from outside is drawn into the heater by the fan, heated, and then distributed through outlet hoods to every corner of the open space. Uses live or exhaust steam. Fan operated by any power available.

Type DF—Where Steam Not Available

Construction is similar to th of Type SC, except that stea coils are replaced by a hea cast iron fire-pot. Burns co coke or wood—no more trou than an ordinary furnace. Co air is forced around the surfa of the heated fire-pot and th gently diffused through outl hoods into the open buildi space.

Get Further Information and List of Users.

Do as the Big Shops do.

Many of the large metal-working shops furnish every employee using hack saws with a Starrett Hack Saw Chart. Use of this chart enables the user to instantly select exactly the right saw for each job.

If, for example, a man has to cut heavy angle iron in a power machine, he asks for Starrett Hack Saw Blade No. 255. Or if the job is cutting brass pipe, he calls for No. 252. If light sheet metal, he wants No. 253. If hand-sawing machine steel, he gets No. 112. And so on.

Using the right blade saves time, speeds up production, reduces blade breakage.

Whether you use hack saws in your home, workshop, or on the job—whether you employ a thousand hands, or use your own—if metal cutting is in your line you need STARRETT Hack Saw Blades, and the Starrett Hack Saw CHART.

Copy of this Chart will be sent you free. Write for it, and ask for the Starrett Book—"Hack Saws and Their Use." It's a book of 64 pages of practical hack saw data worth money to men who work in metal. Copy free on request.

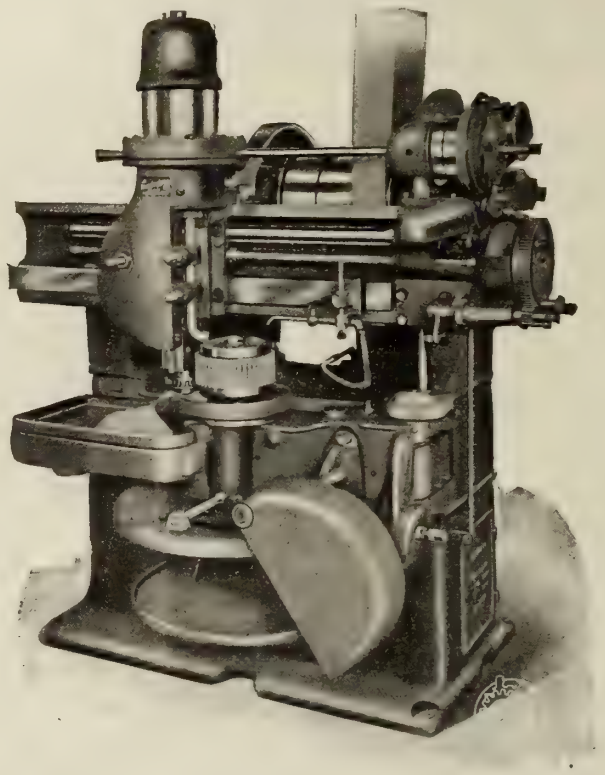
Gear Cutting With the "IFS" Left Out

The Gear Shaper Way



A production manufacturer knows that he will secure good gears IF he has an accurate cutter, an accurate machine and a machine working on the correct principle. The whole question of good gears is resolved in this little word "IF."

When the Gear Shaper was originally designed, the question of "IF" was taken into consideration and every possible means known to mechanical engineering was employed to eliminate the "IFS" from gear cutting.

That we have been successful in solving the problem is evidenced by the fact that each ensuing year sees a larger number of manufacturers adopting the Gear Shaper method.

How the Gear Shaper has accomplished this is clearly explained in our general catalog "Commercial Gear Cutting," which is a treatise on the subject of Gear Cutting with the "IFS" Left Out.

Send for your copy to-day

"Why Don't You Use PHOTOSTAT Prints"

And the PHOTOSTAT makes no mistakes.

It makes photographic facsimiles.

Let us send you a booklet containing letters from many firms telling of large savings through the use of the PHOTOSTAT.

IT is not necessary to carry around large, awkward blue prints for field and shop work. PHOTOSTAT copies can be made either of the blue print or of the original drawing, in a few minutes time, and at a convenient size so that they will fit into a loose leaf book which is easily handled. Furthermore these copies will not fade or smut and being of uniform size can be conveniently filed for future reference after the job is completed.

The installation of a PHOTOSTAT in an industrial plant mans the elimination to a large extent of tracing work, because pencil sketches are copied direct in photographic facsimile; or, if the original sketch is not available the blue print can be copied equally well. Catalog pages, advertising layouts, maps, production charts, test reports, and documents of all kinds are also copied in photographic facsimile by the PHOTOSTAT with a great saving in time and money.

The PHOTOSTAT is made by the Eastman Kodak Co., exclusively for the

Repaired in 5 hours

MAINLY through the portability of Prest-O-Lite it was possible to weld the base of this heavy railroad crane in a few moments less than five hours.

That's the usual quick way in which it is possible to weld with Prest-O-Lite and the oxy-acetylene process.

Through the use of Prest-O-Lite it is possible to weld, build up and cut metals without bringing the work to be done to a workshop.

Thus Prest-O-Lite, the Universal Gas with the Universal Service provides the means for moving an oxy-acetylene welding outfit anywhere and everywhere.

You will be interested in the Nation-wide Service of our conveniently located plants and warehouses.

Machining Delco Generator Frames

The photograph above shows a tool set-up on a Steinle 24-in. Turret Lathe for turning out Delco Generator Frames at the plant of the Delco Light Company of Dayton, Ohio.

The chucking fixture revolves in a steady rest and is equipped with centering and stop pins for centering and locating rear end of frame by pulling sleeve collar forward. Set screws hold the front end in place. The turret fixture is reinforced in the machining operation by the overhead bar support; thus preventing undue chatter or jar under the heavy cuts taken.

This is only one of a number of installations in plants manufacturing electrical equipment where the Steinle is called upon to produce various parts from castings, forgings or bar stock.

In view of present manufacturing conditions it is invarably performance that counts and the Steinle qualities of accuracy, speed, ease of operation, power, reliability and economy of upkeep are guarantees of satisfactory performance on your own work.

Material—Cast Steel
Finish—Bore, Counterbore, Face Bottom, Face Lugs
Time—25 Minutes Each

Why not send us your blueprints if your requirements call for the installation of equipment of this character? We shall be glad to furnish you with production and tooling estimates, or to have a qualified representative call and take up the question of Steinle methods as applied to your production problems.

DIAMOND FIBRE
at
TORONTO EXHIBITION

WE cordially invite every manufacturer attending the Canadian National Exhibition this year to visit our booth in the Industrial Building.

We will be showing Diamond Fibre in all its different forms, both in the raw material and in finished products, as well as articles in which it has been utilized for machined parts in the place of wood, metal, rubber or other materials.

If you are using any of these latter in your manufacturing process it will pay you to let our representatives explain to you how Diamond Fibre can increase your production and decrease your production costs. Our representatives will be at our booth every day and will be glad to answer all enquiries.

We want our out-of-town customers to make the Diamond Fibre Booth their headquarters while in Toronto.

A 3-Way Time Saver on Drilling Jobs

1—**Drilling time**—it isn't necessary to "take two bites of a cherry" when you drill with a Hoefer Multiple Head. Drilling entire groups of holes at a clip instead of a single one at a time is bound to cut huge slices from your drilling costs.

2—**Starting time**—no careful scanning and measuring of alignment; no gingerly feeding of drill down to the work; no shifting of work or bad starts—all these are avoided by the guide bushing that assures a quick getaway in drilling each piece.

3—**Setting-up time**—You don't have to be convinced about the helpfulness of a jig in reducing the time required to get up a job and in improving the accuracy of the work done.

You see this compact little Hoefer Multiple Drilling Unit cuts down the time used in **every** stage of your drilling operations. And **mark this:** the complete outfit in every case is designed by Hoefer, built by Hoefer, and guaranteed by Hoefer—you need not shop around for accessories or make them yourself. If you're looking for better results with any kind of a drilling job, take it up with Hoefer.

Fairbanks-Morse

Type "Y" Engines

Appreciating the demands of power users for economical power, our engineers have developed a line of Semi-Diesel engines in which can be used a great variety of low grade oils, including crude oils.

In construction Fairbanks-Morse Oil Engines combine the great simplicity of the valveless two-cycle principle with accessibility and sound mechanical construction. They are especially adapted to driving dynamos and other machinery requiring a constant steady rotative force.

Some of the special advantages which are incorporated are as follows: Low Fuel Consumption, Low Lubrication Expense, Close Regulation, Quick Starting, Ring-Oiling Main Bearings, Accessibility of Parts, No Water Injection, Water Cooled Combustion Chamber.

Our nearest Sales Office will be glad to send detailed information.

CANADIAN MACHINERY AND MANUFACTURING NEWS

Fixtures Used With Success In Disc Grinding

Parts to be Machined on the Disc Grinder Should be Designed to Suit—Method of Grinding Hexagon Nuts—Grinding a Number of Rods at One Time—Angle Plate Fixture Also Floating Fixture.

By F. SCRIBER

N the June 2nd issue we published an article on disc grinding. In the present material we shall discuss a few ctures used on such a class of work. ere is no need to dwell on the advanges of disc grinding, for this fact is clearly proven in the previous article that we will content ourselves with a scription of the fixtures, and the work ich they perform.

Question of Design

To make disc grinding a success the rts to be ground must, or at least ould be designed in such a manner at as small a surface area as possible presented to the disc wheel. This n quite easily be accomplished by reising such portions of the surface that e not actually needed. For example g 1 shows various parts in common e throughout many plants. The part own at A typifies a simple steel disc hich has a large grinding area, while to the right of this at B, is shown a die with five holes in it. From a comparison of these two pieces it will be apparent that the piece B, is much easier to grind than the part shown at A. C, shows a cast iron bracket on which the surface D, is to be disc ground. This bracket has been recessed in such a manner as to leave a rib around the outside and through the center, this being all that the bearing requires. It will be obvious from this illustration that about two thirds of the surface to be disc ground is thus removed. At E is shown a shelf support in which the surface F has been recessed to eliminate much of the grinding surface. Almost unlimited applications where the area is to be disc ground could be thus reduced are in evidence, and besides reducing the heat generated by having the work in contact with the wheel, it increases the speed of the grinding operation and prolongs the life of the disc grinding circles; therefore it is advisable to so reduce the grinding area of the work wherever practical.

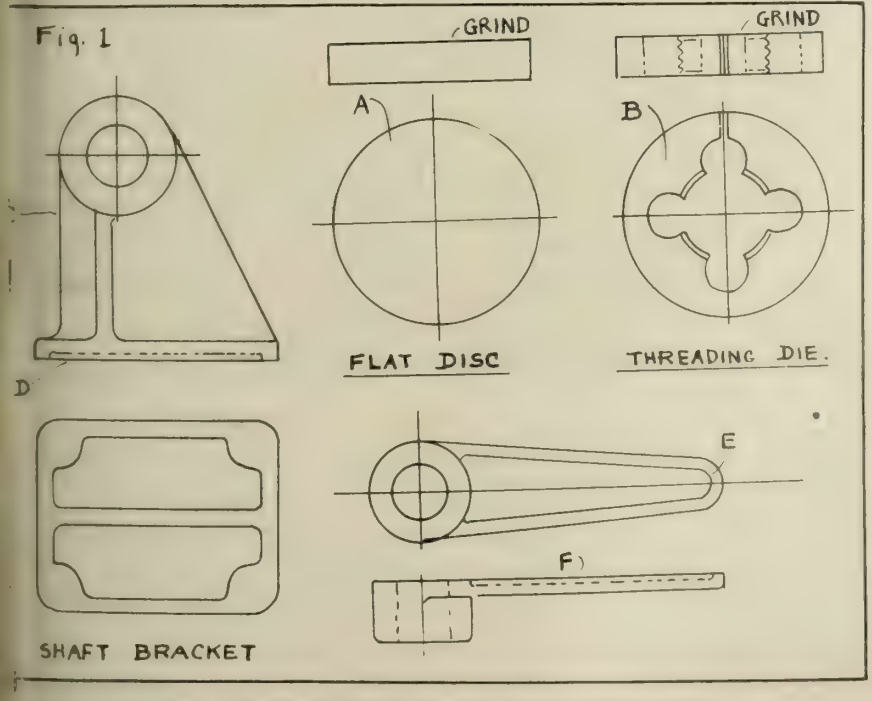

Fig. 1—Showing parts in common use in many plants.

Fig. 2 depicts a holder upon which are mounted six hexagon nuts while the flats on their sides are ground. The nuts are slipped over the hinged rod A, this rod being pivoted at B in a holder C. After all the nuts are placed on the rod it is dropped into position shown; the work guide rest on the disc grinding machine is tilted to an angle of 30 degrees. A holder containing the nuts is then placed in the position shown on the rest D and the sides are ground the flats on the nuts of course accomodating themselves to the flat surface on the disc wheel. After grinding one side they are turned and the next sides are ground. This is continued successively until all six sides are completed.

Figure 3 shows an arrangement which permits of accurately grinding the ends on a number of rods. A vee shaped fixture A is mounted on the supporting table of the disc grinder. A number of rods B are placed in the vee shaped aperture and are clamped therein by means of screw C and strap D. Care is taken to have the ends of the rods practically even and the traverse feed of the machine is used to bring the end of the rods into contact woth the disc grinding wheels.

An application in the use of an angle plate fixture for disc grinding a hal bearing is shown in Fig. 4. The bearing A is held in the fixture B by means of a screw C which forces the bearing back against two screws D and surface E. The bearing in the position noted is then brought into contact with the disc grinding wheels by means of the traversing slide on the machine and is forced against the face of the grinder in the usual manner with a rocking motion. In grinding this half bearing it will be noticed that there are only two narrow surfaces to be ground thus making it an ideal part for disc grinding.

Intelligent Application

The intelligent application of a disc

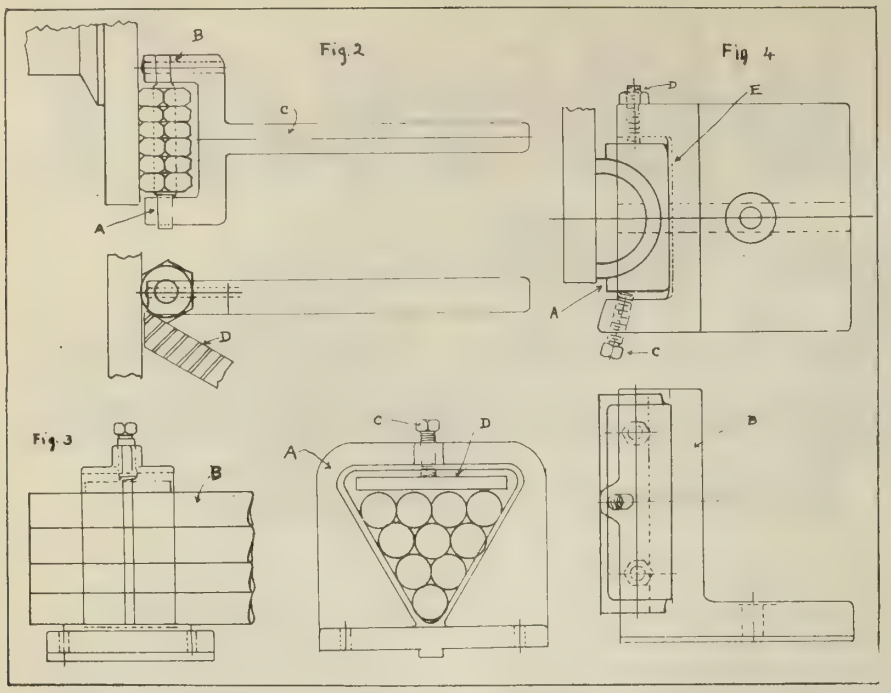

Fig. 2.—Holder for six hexagon nuts. Fig. 3.—Method of grinding the ends of rods.
Fig. 4.—How to use the angle plate with the grinder.

grinder is in a large measure responsible for the success attained. Simple fixtures such as described greatly enhance its value. A disc grinder is not by any means a rough and tumble apparatus but a machine capable of remarkable results on the class of work to which it can be conveniently applied. The amount of material that should be removed varies with the class of work that the machine is applied to. On steel punchings it would probably run from .005, to .015 in., while on cast iron parts it might range from 1-32 to 1-16 in., and often it is necessary to allow for any finish on the pattern.

By referring to Fig. 5, an idea of the utility of the work supports and slides commonly found on disc grinders can be obtained. Figure 5 illustrates a block A being disc ground. This is held in a fixture having a base B clamped to a slide C on the machine by screws (not shown). The work is held by a strap D tightened by a knurled nut E. A lever F brings the work into contact with the wheel and should it be desired to tilt this slide C and work on an angle, it may be readily done by pivoting the bracket G containing the slide C on the center stud H. This bracket is clamped in the desired position by means of the screw and nut J. The work is then caused to traverse across the surface of the wheel, which causes the entire arrangement to pivot on a stud thus imparting a rocking motion to the work diagonally across the disc grinding wheel.

It is generally accepted that disc grinding should be done dry because water will destroy the grinding circles. It is also very desirable that an excessive amount of generated heat be avoided in grinding, as this prevents distortion of the work, also because cool metal grinds easier than warm metal. A metal that is excessively hot tends to destroy the grinding circles. One of the best preventives of heat generation is to keep the cutting circles very sharp and clean, a good stiff wire brush is generally used for cleaning the grit out of the circles.

Fig. 6 shows a method of grinding work on centers on a belt polisher. This consists of two strips of steel A containing centers B. The two strips are riveted together with pins at C, the work D is held between the centers B, it being sprung into the position shown by holding the strips A apart by hand. The work in the holder is then held in contact with the polishing belt and revolves on the centers while being polished.

Floating Fixture

In many cases it is necessary to s hold the work that a floating featur must be incorporated in the design o the fixture. This is made necessary b the fact that a flat surface is to b ground in its natural alignment wit other portions of the part being ground Fig. 7 shows an arrangement embody ing a floating feature. The work i mounted on the face plate A over a pin B or other suitable arrangement The end of A is ball shaped at C, an fits into a similar shaped recess in th angle bracket D. A plate E, made in tw halves, is screwed into the positio shown and holds the work holding plat A in position, while the ball featur allows it to rock. A spring arrange ment F provides sufficient tension s that the face plate A is prevented fro floating too freely. This entire arrange ment with the work is held on the tra verse slide of the disc grinder and whe the work is brought into contact wit the grinding disc, the fixture, throug this floating medium, allows the wor to assume a natural position corres ponding in a general way with the shap of the surface ground on the work.

A work holder for general utilit purposes is shown in Fig. 8. This con

sts of a flat piece of steel having a le handle on its end. Into this piece steel are riveted three pieces of pipe Three parts which have holes in iem are slid over these pieces of pipe id disc ground at the same time, being eld in contact with the disc grinder y hand while this is done. A larger mber of pipes A might be employed epending upon the nature of the work, nd it will be found useful in disc inding to have a variety of simple pliances on hand for general util- y purposes.

Some disc grinders are made with two heels adjustable towards a common nter, These will grind both sides or ds of nuts, collars and other suitable rts at the same time. Figure 9 is example of this class of work where e wheels are shown at A & B; the work ia bushing C which is recessed; a spring lk D grips the work over this recess, d the bushing C is fed by hand be- teen the two discs and both sides e ground in the manner illustrated. It quite general to use suitable hoppers magazine feeds for handling work this type of machine.

LLING-MACHINE FEED SYSTEMS.

By J. AIREY.

n looking into the literature on the ject of milling-machine feed systems ave been much impressed by the lack systematic investigation, and even, quently, of reasonably straight analy- s in connection with the data already and. A case in point, not so much nected with the action of a milling cutter as with the functioning of a milling machine, is the question of the two types of feed systems. This was brought more distinctly to the fore by the definite stand taken in a recent article in favor of a machine driven from the spindle. The best current practice has rejected this feed system. The new system of constant-speed feed shaft lends itself to very rigorous demonstration as being in all ways superior to the system formerly in vogue.

There are two different systems of feed mechanisms used in milling machines, continues the author in a recent issue of "Practical Engineer." The older one has the feed mechanism driven from the spindle of the machine. The modern method uses a separately driven feed shaft running at constant speed.

The following six statements are submitted in logical sequence, some being axiomatic:—

1. In discussing the action of milling, feed per tooth is the fundamental quantity.

2. A large-diameter cutter will have more teeth than a small cutter.

3. One tooth in a large face mill will take a heavier cut than a tooth in a small end mill.

4. Peripheral speed is approximately constant for a given quality of cutter and of material. It follows that the large-diameter mill will be used in conjunction with slow speeds and small-diameter mills in conjunction with high speeds.

5. A large-diameter cutter will call for a larger feed per revolution than a small-diameter cutter does. (See statements 2 and 3.)

COPPER-STEEL.

In a paper read before the American Iron and Steel Institute, E. M. Buck reviews the development of copper-steel, stating that tests made by a committee of the American Society for Testing Materials with the co-operation of the United States Bureau of Standards, together with other data available, prove that by alloying from 0.15 to 0.25% copper with normal open-hearth or Bessemer steel the rate of corrosion of steel is very much reduced, where the products are exposed to alternate attacks of air and moisture. It is also claimed that in the investigations indications pointed to a better adherence of paint coatings on copper-steel, resulting in a more effective and longer-continued protection by the paint film. The manufacture of copper-steel has heretofore been largely confined to sheet metal, but it might be extended to other uses. In particular, steel freight cars are mentioned, especially those of the open kind, which are greatly affected by corrosion.

A large water-power station is at present being built at Ætsä, Finland, about 70 kiloms. east of Bjorneborg. It is said that a transmission line will be laid down the whole of that distance to conduct about 7,000 H.P. to the industrial establishments at Bjorneborg. The power station, which is being built by the Bjorneborg Power Company with a capital of 2,000,000 Finnish marks, is expected to be ready this month.

ELECTRIC HEATER.

An ingenious electric heater for the starting of crude oil engines is a new British invention. The device is said to be extremely simple, and consists essentially of an electric heating element of high resistance wire placed in the line of action of the oil spray. A small amount of current suffices to make this wire white hot, in which condition it brings the spray rapidly to the temperature required for starting. After the engine has gone ahead the element is withdrawn, so that it is not exposed for more than a minute or so to the high temperature of the combustion chamber—an arrangement which gives it long life and great reliability. The electric current required for operating the heater is supplied by a 4-volt or a 6-volt battery charged from a tiny electric generator, driven through a bolt from the engine. By means of this device the engine can be quickly started up from cold without the slightest trouble. Twelve months trial of the apparatus has shown it to be thoroughly satisfactory.

John Conley Tackles Machine Shop Problems

Making a Lathe Fixture For Small Eccentric Shaft—Simple Device Was Sufficient to Produce the Work—Making a Test Tool to be Used For Producing Certain Vee Blocks.

By J. DAVIES

"WELL, John, what do you know this morning?" was the cheery salute of a shopmate one morning as John was sitting on the end of the lathe bed examining very critically a blue print he had in his hand.

"What do I know? I know nothing—and I know it well."

"What seems to be the trouble?"

"You know the small eccentric shaft I made for that flour sifter I had such a time with?"

"Yes, I remember."

"Well, along comes the boss this morning with an order for 100 of them, but he says he is going to turn them over to the production department."

"Well, that lets you out, doesn't it?"

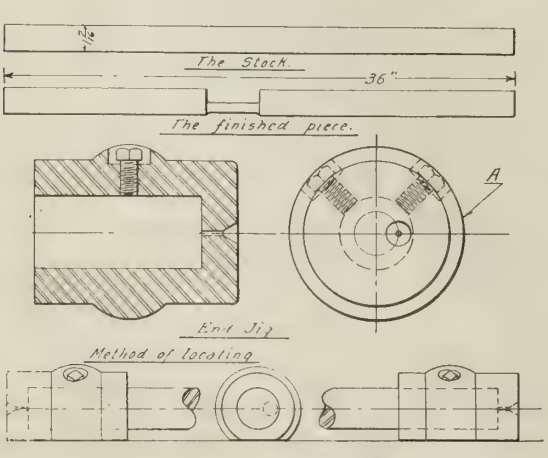
"Not much. He says it is up to me to make a jig, so that any lathe hand can do the job in about one-third the time it took for the first one. Of course I have seen lots of fixtures around the shop, but I have never seen any for lathe work."

"Well, John, I consider the boss has paid you a compliment. I once read that there was nothing new under the sun and that all inventions were new applications of old principles, so you might get an idea from other fixtures already in use."

John was determined to show the foreman that he had more ambition than to be always a lathe operator, so considered this question very carefully and suggested to the foreman a general plan of operation, which after some slight modification was carried out as follows:

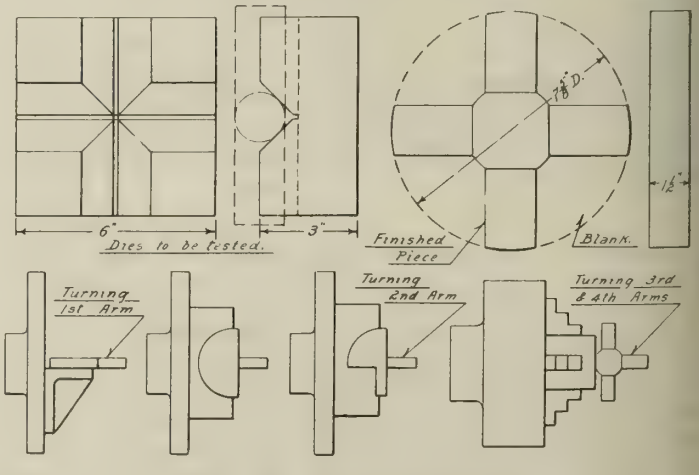
The shafts were made from 1 7/16-inch diameter cold rolled steel about three feet long. Two pieces of tool steel were bored a push fit for the ends, one for each end. A piece of cold rolled steel, large enough to allow for turning, was driven into an old flange, after which the flange was faced and bolted to the lathe face plate. The piece driven into the flange was turned to fit the two pieces already bored, they being the exact size of the cold rolled eccentric shafts, for which the jig was being made. Two holes for set screws were drilled and tapped at right angles to each other in the steel pieces A. The screws were sunk below the surface, and the holes countersunk for a box wrench, to avoid accidents through projecting set screw heads.

The jig piece, A, was next fastened to the turned mandril by two set screws. The end was faced true and smooth and a very fine circle was made on the end with a sharp pointed tool equal in radius to the required throw of the eccentric shafts to be turned. A horizontal line was drawn through the centre, right across the face, and where the horizontal line cut the circle was the centre required.



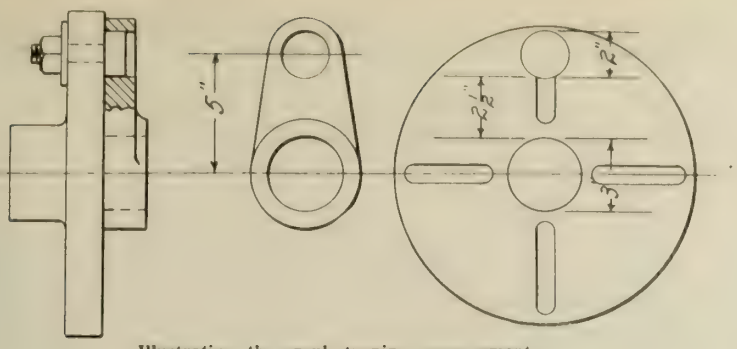
Probably the most accurate method of marking off a horizontal line to cut the centre exactly is to take an old square file and grind it to a sharp point. Place it in the tool post as near the centre as you can guess, then make a horizontal line across the work. Turn the lathe halfway round and test with your pointer, making another line exactly parallel with the first one. If the lines should come exactly on top of each other you have hit the centre first time. If not, and you make two distinct lines, then the exact centre lies midway between the two lines and you adjust your pointer accordingly.

With this point as centre, make a circle with the dividers for setting up by, slacken the bolts and slide the jo to the new centre, setting it very car fully. Now make the centre with a to and put in a very small drill to cle the point, repeating the operation wi piece No. 2 for the other end.



Both pieces are now exactly alike, t only thing that remains being son ready method of locating them on t shafts in proper relation to each othe This is done by placing them on a sho piece of shaft and setting them up t the horizontal lines on the planer shaper, and shaping a flat on one si of each piece. In use the jigs are plac on the shafts and the flat spots plac on the lathe bed, planer or any oth flat surface, and the set screws tigh ened up, when the job is ready to turned. The same jig pieces can be us for several different throws if the ce tres are not too close together.

To John's delight the jig gave eve satisfaction and proved to be a ve quick and accurate method of turni these eccentric shafts. After this su cess John was given another lathe a tachment to make. This time it was bore out a number of cranks, with three-inch hole for the crank shaft, a a two-inch hole for the crank pin, at exact distance of five inches apart fro centre to centre.



The first thing he did was to turn a pin with a round head, a nice fit f the two-inch gauge ring, leaving a sha threaded at the end for a nut to tight it up in place. He next put the thre inch standard plug in the lathe betwe centres and tested it with the indicat to see that it ran perfectly true. I then placed the pin he had turned wi a two-inch diameter round head in t slot of the face plate, and moved it

The jig used for shaft.

How John made the precision tool.

Illustrating the crank turning arrangement.

a) down until he had it set exactly
s and one-half inches from the three-
in plug between the centres, measur-
in between the two inside edges with
ch inside micrometers. This ensured
hn being exactly five inches apart,
e re to centre. After tightening the
o ting pin in place, he drilled two
rill holes in the head and put in dowel
i to keep it in place.

ow the method of operation was very
ible and extremely accurate. First
placed the three-inch hole over the
o ting pin and set the two-inch hole
proximately true with the casting,
ced the work to the face plate and
hed the two-inch hole to the stand-
r plug. He then reversed the work
placed the finished two-inch hole on
locating pin, which automatically set
xactly five inches centre from the
r hole, then bored out the three-inch
and repeated the operation for
y piece.

he next job John had to tackle was
ecision tool to be used in testing the
racy of some Vee dies being fin-
l on the miller. These dies consist-
f a square block of steel about disc
s square and three inches thick with
w 90-degree Vees cut right through at
angles to each other, perfectly
llel to the base and square to each
r. The test tool was made from one
e of steel and had four arms as
n in sketch, these arms were all
same size and were square and true
each other every way. This tool
simply placed in the die and tested
he surface plate with indicators and
ers. This piece of work was too
u for John's ingenuity, and, as he
essed it, it was a regular Chinese
le and got him all balled up.

ter several trials he found that he
not mark off the four ends exactly
e right relation to each other, and
if he had succeeded in doing so, to
in four centres and maintain that
ion was very unlikely. So he con-
l with the foreman and he in turn
it the drawing office, and the method
achining this piece was decided on
llows:

st, a perfectly flat surface was
on one side, then a true angle
was bolted to the face plate of the
the correct distance below the
c. The piece of work was now
l to the face plate with sufficient
anging to make the length of one of the arms. This arm was then turned to the finished size. Before taking the finished cut the work was checked over with the feelers to see that it was bolted down perfectly flat on the angle plate.

In the second operation the piece was turned round 90 degrees and bolted down on the angle plate exactly the same as for the first operation. The second arm was next turned in the same plane and at right angles to the first arm. The test for right angles was made by putting an indicator in the tool post and slowly pulling the lathe round so that the finished arm, now lying parallel to the face plate, just touched the indicator and registered the same at both ends of the finished arm.

The third and fourth arms were turned by placing a piece of cast iron scrap in the chuck, which was bored out a tight push fit for the finished arms. Before placing this piece of scrap in the lathe, a hole was drilled and tapped for a set screw and partly plugged up with a piece of brass, so that the point of the set screw would not damage the finished work. The first and second arm were pushed into this piece prepared to receive them, and the third and fourth arm finished.

This completed a very accurate test block with the arms all square to each other and lying in the same planes.

A PORTABLE ARC WELDER

The Electric Arc Cutting & Welding Co., Newark, N.J., has developed a welding machine weighing complete 100 pounds, which, with reasonable care, will accomplish any work in or around a garage or garage machine shop, etc. The machine will use electrodes from 1-16-inch to 5-32-inch and will operate continuously with the medium and small sizes, and intermittently on the large sizes. Standard lines of machines are built to operate absolutely continuously, but careful design and development produced this machine, which will fill any and all the requirements for automobile repair work, plumbing shops, sheet metal work, electrical shops, etc.

It is also very handy in a job welding shop where electrical experience is available and discretion is used as to its capacity. Every available care is taken to reduce the weight and maintain its capacity. It probably has not as many limitations as one would be led to believe from the foregoing. The only point is, it cannot be guaranteed on a heavy boiler or engine job for continuous duty, although it will do such work if used with discretion, and with proper discretion, the machine will last a lifetime. Its portability was forcibly brought home to us by a picture of a man holding a complete outfit under his arm.

This machine will operate on either 110 or 220 volts, and any frequency specified in the order, and the machine can be made for other voltages, but the standard worked up design is for both of the voltages mentioned, that is, there are two coils in series on 220 V and in multiple on 110 f. The power supply must be of at least 5 KVA in order to use this machine, and be within the underwriters' regulations. While it will operate from a lamp socket with the smaller electrode, it is not allowable or good engineering to do so. If 5 KVA is available, however, it will operate connected to the panel board from which the lights are distributed. It will operate for less than 1 KWH per hour or in general less than 3c an hour.

The connections are very simple. Two wires are hooked from the machine to power supply and two other wires which are furnished with the machine are attached to a plugging in board unit mounted on the machine for regulation. In order to make the machine standard there is included in each machine provision for operating on the following volts.

The uses to which this machine may be put cover every field of arc welding that could be encountered except perhaps doing very heavy work rapidly, as above voltages—90 to 130 volts and 180 to 260 stated; however, it will do the heavy work but at a reduced rate, i.e., not economical for production, but at a rate perfectly economical for emergency repairs.

Around a garage or automobile repair or machine shop, the uses to which this machine can be put are as follows: Repairing of scored cylinders by spotting and peening with a nickel electrode, and straight repair welding of cracked and broken blocks, and mudguards, mudguard brackets, cracked water jackets on cylinders, broken frames and other chassis parts such as lamp brackets, bumper brackets, tire holders, step brackets and any part around the chassis which has become loosened due to wrenching or wear, may be tightened up forever with this machine. Squeaks and rattles otherwise impossible to get rid of, can be cured forever with this machine. In the automobile machine shop, parts that would have to be bushed or replaced can be built up to beyond their original dimensions and machined down to their correct size. Other broken parts such as crank shafts, connecting rods, universals, worn teeth either gears or connection dogs, or anything worn in or about the car, can be built up and machined back to its original dimensions.

Governing Production of Heated Products

Certain Factors Are Involved—Equipment and Fuel Should Be Selected To Suit Individual Plant Conditions—Principal Factors Are Grouped Under Three Heads—Chart of Value is Given.

By J. A. BROWN

IN the production of a heated product, particularly that in which heat treatment is a part, it is necessary to select that form of equipment and fuel adapted to the individual plant conditions, which when properly combined and operated will produce the result sought. In general terms this may be summed up as producing a finished product of given quality at minimum cost.

To produce this result the principal factors to be considered may be grouped under three principal heads; the first is the quality of finished product; the second the facilities available or required to produce this product, these in turn determining the cost of the finished product.

The quality of the product depends upon the raw material and upon the heat treatment it receives. The term raw material is here used in its economic sense in that the finished product of one group of producers becomes the raw material of the following group. Each step requires a definite combination of material, process and skilled effort for its transformation. Raw material, before heat treatment, includes material more or less fabricated, having been cast, rolled, or forged at working temperatures considered suitable for these operations but with, perhaps, indifferent or little attention given to the resulting structure or condition. The chemical analysis probably checks within the limits required by the specifications, but the physical properties and structure may indicate considerable lack of uniformity in the material submitted to heat treatment. This condition merits far more attention that it has received, as every heat treater is familiar with many instances in which the after treatment is expected to restore those properties that have been sacrificed in working the raw material.

Heat treatment is commonly understood to consist of a definite succession of heating and cooling operations and the heat treatment as a process is good or bad to the extent that these operations are made definite and that the variables involved may be controlled. Control requires the duplication of condition and results and demands a high degree of standardization. Thermally, heat treatment simply covers an interchange of heat, and the thermal action is between two substances, one giving up heat and the other receiving it. A hotter fluid, flame or substance surrounds or plays on a cooler substance or object and, due to the difference in temperature, the cooler object becomes heated and the surrounding substance loses heat. The manner in which the heat is applied determines the uniformity with which the heat is absorbed.

In order that the change in the structural composition of the metal may be unobstructed, it is a fundamental requirement that the heating and the cooling should be uniform. Uniformity in heating produces the required structure in the least time with the least expenditure of heat energy, while uniformity in cooling fixes the final structure composition.

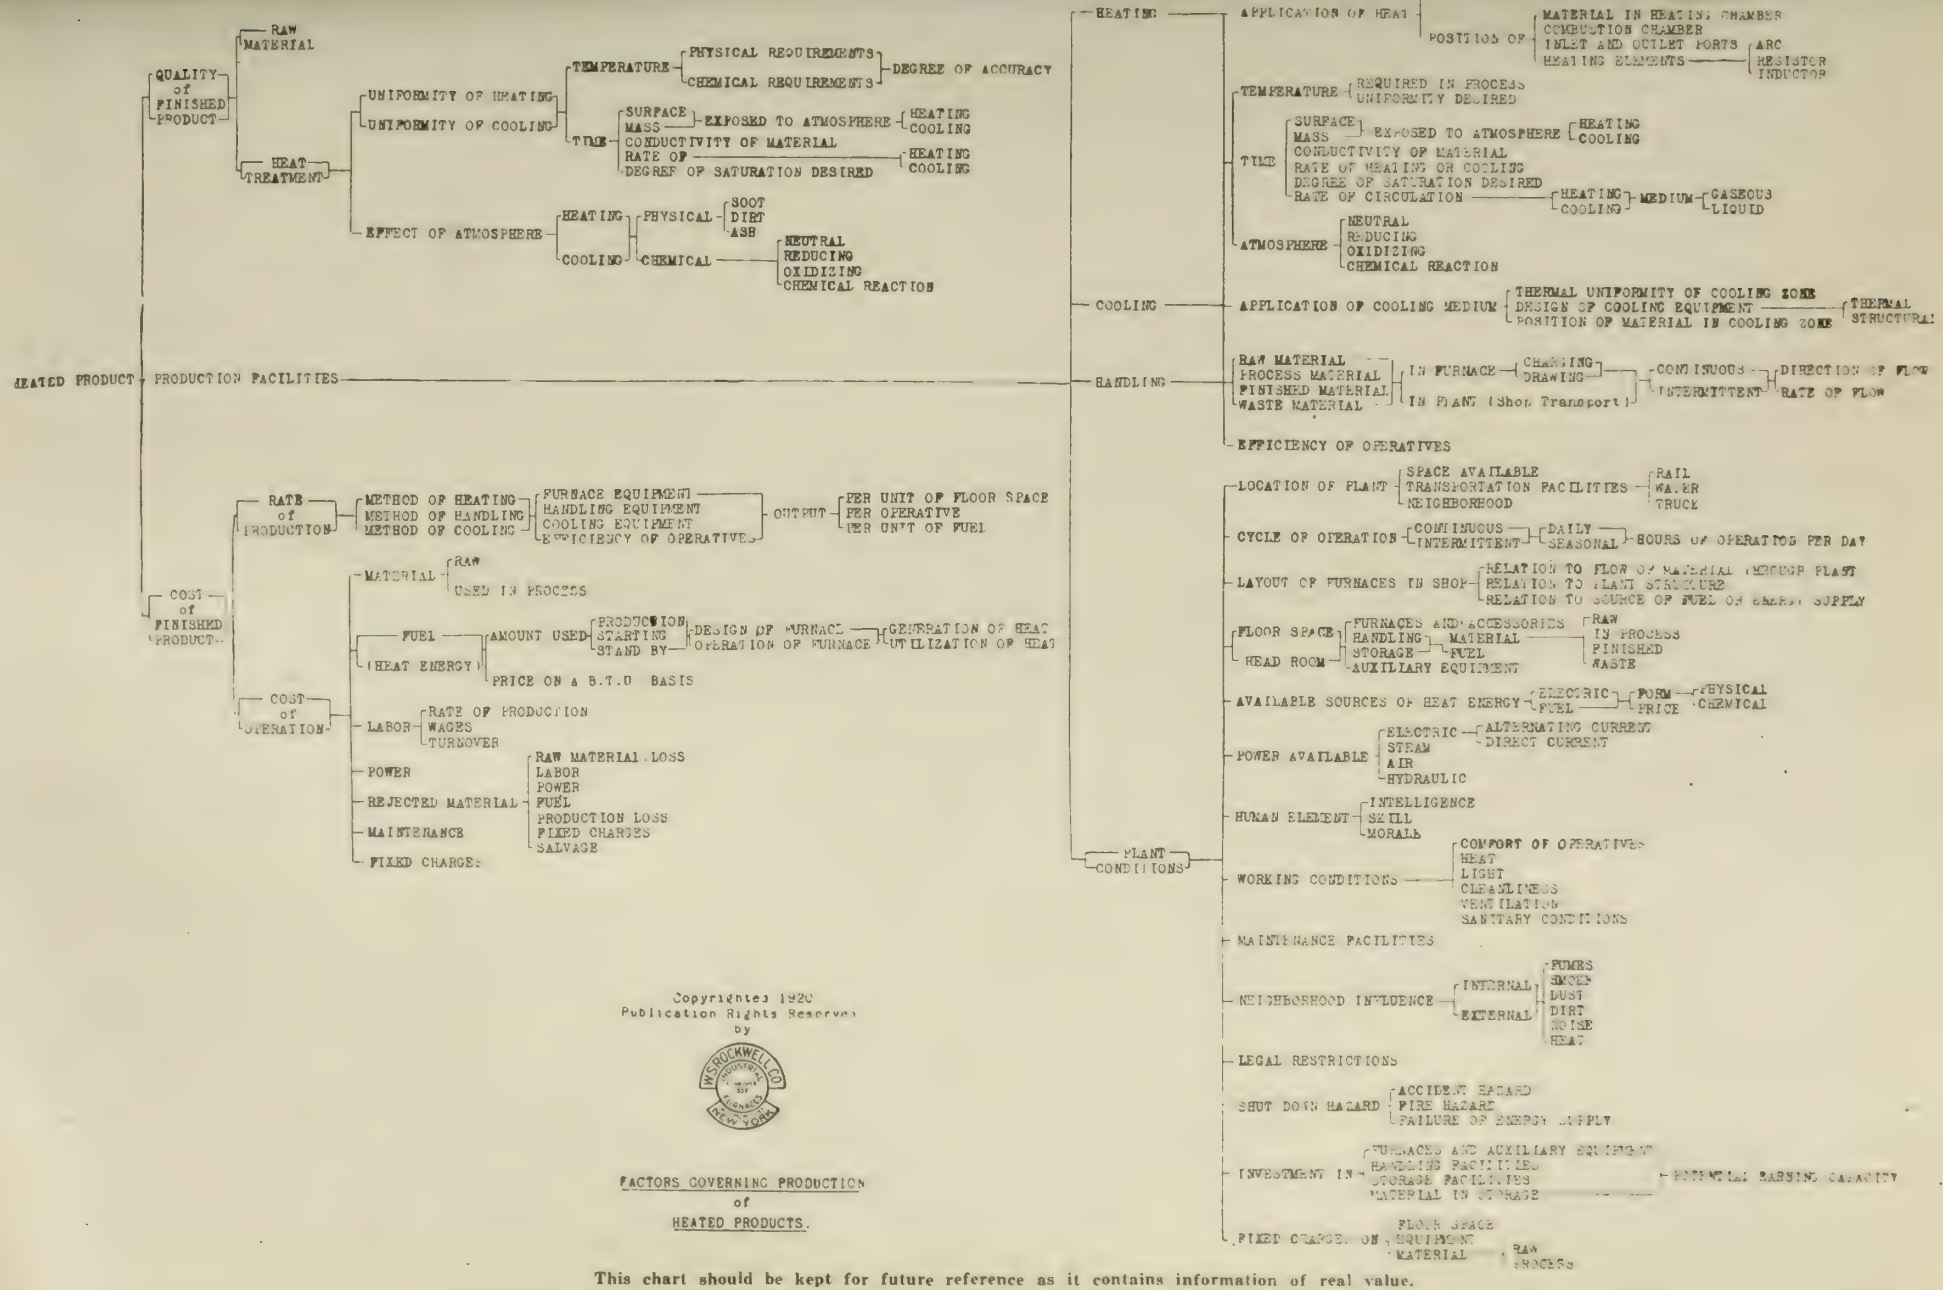
POINTS OF IMPORTANCE

Three factors must be considered, viz., the quality of finished product; facilities available or required to produce the product, these in turn determining the cost of the finished product.

The temperature variation in and around the piece being heated and the degree of accuracy with which this temperature variation may be controlled determines the uniformity of heating. Equally important is the time in which the material is heated or held at temperature before cooling.

Plant conditions not only affect the quality of the output, but may materially affect the cost of a finished product. This condition should therefore be considered in detail as part of the production facilities.

Temperature Required.



For every piece subjected to heat treatment this question must be answered: "What temperature is required?" and a workable answer depends upon data of various natures resulting from actual investigation. Fundamentally, it is a question for the metallurgist to answer correctly and fix the degree of heat required in a given operation. In a physical sense, the temperature variation in and around the piece being heated and the degree of accuracy with which this temperature variation may be controlled determines the uniformity of heating.

Equally important is the time in which the material is heated or held at temperature before cooling. Time depends not only on the mass of the material but on the surface exposed. [illegible] relation of mass and surface is a fu[illegible] tion of the shape and it is readily [illegible] preciated that an irregular shape w[illegible] unequal metal thickness, offers m[illegible] difficulties than a simple shape of [illegible] form thickness. Heat transfer can [illegible] take place where a temperature dif[illegible] ence exists. The greater the temp[illegible] ture difference, the more rapid the fl[illegible] As the difference becomes less the [illegible] decreases until equilibrium or sat[illegible] tion is reached. Obviously the temp[illegible] ture in the heating zone should not [illegible] higher than the temperature requ[illegible] for the operation or process, thoug[illegible] is evident that a longer time will be [illegible] quired to heat. In forge shop prac[illegible] high temperature and incomplete [illegible] uration are responsible for the so-ca[illegible] wash heats, where the surface of [illegible] metal may be dripping and yet a h[illegible] core will be found in working un[illegible] hammer or press.

The atmosphere in the furnace ha[illegible] very direct effect on the quality of [illegible] ished product. This atmosphere or c[illegible] dition in the furnace may result fr[illegible] the fuel used or from the conditi[illegible] under which the fuel is burned. S[illegible] and ash result from the physical co[illegible] tion under which a fuel is used, a[illegible] indicating unconsumed fuel. Ash is [illegible] quently a troublesome feature, w[illegible] coal is used in powdered form. So[illegible] operations require a clean fuel and [illegible] find anthracite in use in the soft c[illegible] districts and natural gas in the cera[illegible] and glass industries of the Middle W[illegible]

At times it may be necessary to p[illegible] tect the work from contact with the f[illegible] nace gases and in this case muffles [illegible] refractory materials are employed. T[illegible] atmosphere within the muffle may [illegible] oxidizing or reducing, though usu[illegible] oxidizing. Enameling, glazing and si[illegible] lar operations are conducted in [illegible] way. Vitreous enamels may be made [illegible] the electric resistance furnace but [illegible] the arc furnace, the gases from the e[illegible] trodes are very liable to have a reduc[illegible] effect upon the oxides in the enam[illegible] Special atmospheres to control a ch[illegible] ical reaction are obtained by the use [illegible] muffles filled with gas or superhea[illegible] steam. Atmosphere is not due to a[illegible] particular fuel or type of furnace, [illegible] depends entirely upon the air supply [illegible] a given fuel. Where the air supply [illegible] less than that theoretically required [illegible] combustion, so that the gases in [illegible] heating chamber carry no free air [illegible] contain a small percentage of fuel ga[illegible] reducing atmosphere is maintained.

FACTORS GOVERNING PRODUCTION
of
HEATED PRODUCTS.

This chart should be kept for future reference as it contains information of real value.

Production facilities must be provided with regard to the manufacturing requirements and in harmony with the plant conditions. For a given quality of output, the heating, cooling and handling methods must meet the requirements of the process.

The application of heat is not an abstract question or one to be determined from a discussion of fuel values or combustion, nor is the heat balance a real test of the equipment. The application of heat is essentially one of dynamics for heat flow and the thermal condition around a mass to be heated is not determined by the temperature indication at one or more points in the furnace. The stress that has been laid on uniformity of temperature in the chamber leads to false conclusions inasmuch as the temperature at any particular point represents what might be termed a static condition, while fundamentally we are concerned with the transfer of energy and not the indication of temperature. The real condition governing the design of the heating chamber is that the heat be uniformly applied to and absorbed by the work.

Absorption of Heat.

Absorption of heat varies with the position of the material in the heating chamber, the location of the combustion chamber in relation to the heating chamber, or, in electric furnaces, to the position of the heating element in relation to the charge. Many electrically-heated furnaces, particularly those of the semi-arc or resistance type, function in the same way as a fuel-fired furnace. The product or material in the furnace is heated by conduction and radiation. The electric energy is used to heat the resistor, which in turn transmits the heat to the product by the atmosphere or by radiation. The laws governing the movement of the gases in the heating chamber are the same with either form of energy. With electricity as with fuels, the uniformity of heat throughout the chamber and uniform heating in the chamber do not necessarily go together, as the result is a function of design and operation and not something inherent in the energy itself. It may be said, however, that electric energy in some form of special equipment can accomplish results not possible with any form of fuel-fired furnace.

In one sense there is no absolute uniformity in the temperature of the gases in the heating chamber. From the time combustion is completed and until the gases leave the heating chamber, they are giving up heat, and at the same time, decreasing in temperature. This condition determines the position and design of inlet and outlet ports. Hot gases rise and must therefore be pulled down; cold gases fall and must therefore be pushed up. The high velocity of gases, due to a temperature difference, is not generally appreciated. It is evident that the heating conditions, when the chamber is empty, are very different from those existing when the chamber is full. In many cases the chamber is so overloaded that the flow of heat becomes essentially that through a series of flues, and consequently the placing of the charge should follow the fundamental requirement that a hot gas when cooling should go down; a cold gas when heating should go up, and this condition of flow be fixed by the location of the ports.

How to Reduce Rejections.

Most malleable iron annealing furnaces are packed too solidly and often times the rejections would be materially reduced by the use of a smaller charge placed with more open space between the saggers. In some periodic kiln operations, a virtue is made of necessity, due to improper application of heat, for instance, abrasive wheels are graded by their degree of burn due to their position in the kiln. The same defect in placing the charge is often observed in carbonizing furnaces and is aggravated by the relatively short time required for the carbonizing operation. There is no excuse for this practice in open chamber heating and from a pile of pieces in one charge, it is often possible to pick out two or three distinct degrees of heat.

The same considerations that govern absorption of heat by the work apply with equal force to the cooling or quenching of the work. Where the work is cooled by quenching the action may be much more drastic in its effect on the steel and therefore requires more refinement in the details of handling. Heat gives the structure, cooling fixes it. Heating should be slow and may be prolonged with less injury than where the heating is too fast. There is not the same flexibility in the cooling operation which must be performed with more precision in point of time. Heating and cooling may be more or less automatic through the mechanical handling of the work, and the same consideration of the effect of surface and mass upon the time and temperature should be given to the cooling or quenching process that is given to the heating.

As the size of the work increases, the difficulties of heat treating largely are those of handling the material. The mechanical handling of hot material gives rise to quite a different set of conditions to those met in handling cold material. Each definite range of temperature requires the development of a satisfactory method of handling. The methods of handling molten steel have been practically standardized for each particular process. The making of brass castings follows a common procedure. There are no standard methods in handling a heat treated product as each instance must be dealt with on the ba of fuel and furnace adapted to the wor In many ways, the difficulties of han ling the work are lessened when t transfer is made on a horizontal pla with little or no change in the worki level during the operation. Furnac used in connection with sheet rolli mills often have the hearth line at t same height as the roll. Forge furna have their hearth line at the level of t hammer or press dies.

Plant conditions not only affect t quality of the output but may mate ally affect the cost of a finished prod and should be considered in detail part of the production facilities.

In the location of a plant the cost land is seldom a determining fact Contour may be taken advantage of certain operations. Level ground hillside may have particular featu desired for certain processes. A diff ence in elevation may permit the co veying of material by gravity or aid t disposal of waste. Low undrained sp may be used as a dump for waste m terial.

The space available fixes the type construction and may lead to a one-st building or to a concentration in a hi story building. In a high story buildi the flow of product may be vertical, fr top down, instead of horizontal. In t manufacture of many lines of small me parts material received at the grou floor is raised to the upper floor a then progressively descends while bei processed until it is finally packed shipment at the same level on which was received.

Transportation Important.

Transportation is of importance a vitally so at the present time. Wh freight rates on different classes of co modities have a marked influence, th must be a general balance between r material and the market for the finish product, with power, fuel and oth items shifting the fulcrum of this b ance. Nearness to source of raw m terial and nearness to final mark should be considered. Nearness to s cial labor markets have settled spec trades in certain localities, for instan the brass industry in the Naugatu Valley. Fuel or power may be det mining factors as the cheap power velopment at Niagara, cheap fuel Pittsburgh, and water power in N England. In general, rail transpor tion is preferred to water for nearly purposes, as the latter is often inope tive for part of the year.

The general tendency is for a sm plant to locate in a city of suburbs. a large city, while the labor supply m be plentiful, it is apt to be inferior quality and unsteady. At the same ti such location usually offers the adv tages of fire and police protection, wa supply and sewarage. A location

tween two near cities is affected by the high labor turnover due to the general floating or drifting of labor from one city to the other. In general the tendency as the size of the plant increases is away from the city leading, in some cases, to an isolated industrial community.

The cycle of manufacturing operations may require that two or more departments be adjacent or in definite relation to each other, or it may require one or more passages of the work through one of the departments, as an annealing operation following successive machine operations. Layout requirements should, as far as possible, be in harmony with those conditions tending to reduce fire and accident hazard. Where possible operation should be continuous rather than intermittent and this is determined by the size of the furnace as well as by the process and the temperature required. The operation may be continuous, as that of a blast furnace, or an intermittent operation may be carried on continuously as in the open-hearth furnace or an intermittent operation as malleable iron annealing or burning ceramic ware where the charging, heating and cooling cycle may extend over a period of several days. One of these operations would be practicable on an eight-hour basis with a shutdown at night.

Since the furnace operation is but one of the sequence of the manufacturing operations, it follows that the furnace should be located in its proper point in the order of operations, although in general this sequence is due to the economics of handling rather than the particular geographical position, and the internal transportation system of a plant determines the relative position. The question of location is usually one of compromise or a balancing of alternates. Work is brought to and taken from the furnace. Its form may be the same or different as in a melting furnace or a cupola where solid raw material is charged and the charge in a liquid or molten state is transferred to another point.

Fuel is brought to the furnace and, in the case of solid fuel, ash or refuse is removed. Just how far it is desirable to locate the fuel supply in relation to the furnace, depends on the character of the fuel. Fuel oil, from its nature, is readily and cheaply distributed through a plant at small cost for pumps and pipe lines. Gas has similar advantages in distribution. Cold washed producer gas may be piped through a plant as required. Hot producer gas must be used comparatively near the generator. Energy in the form of electric current is very flexibly distributed. With solid fuel the cost of handling is large compared with the cost of the fuel. This tends to place the furnace in close proximity to the fuel supply.

In the grouping of furnaces, a single process leads to the simplest and most compact grouping. With several processes underway at the same time, an entirely different arrangement of floor space, different methods of handling and even different fuels may be required. The facilities for handling the fuel may require as much space as the furnace and the auxiliary equipment becomes a large item in the required floor space. An electric heating furnace may require a transformer that takes up more space than the furnace.

In general the sources of heat energy available for industrial purposes are those fuels provided by nature; coal, wood, oil and natural gas, or electric energy from the above fuels or from water power. Coal may be used in its raw state; it may be powdered, which changes its physical form but not its chemical form, or it may be gasified, changing its physical as well as its chemical form. Depending upon the method of gasification, coal is the basis of gases having widely different qualities ranging from producer gas with a low B.t.u. content per cubic foot through various mixtures of coal gas, producer gas or water gas under the general name of fuel gas. Coal gas in general has the highest B.t.u. value per cubic foot while blue water gas, intermediate in value between producer gas and coal gas, gives a higher temperature.

A fuel to be commercially available must have a form, value and price that will permit its use in the particular form most suitable for the purposes desired. The unit cost of gaseous fuel is much greater than that of the solid fuel from which it is obtained but due to its form value, the gaseous form permits a reduction in the net fuel cost per unit of product. Fuel is here considered simply a source of latent heat energy without taking account of its commodity value. The principles governing the application of heat and the factors entering into the result are the same in electric heating as with other fuel, and while the flow of electric energy is readily controlled it must be realized that this does not imply the same degree of control in the application of the heat produced.

Power Available.

The power available may influence the type of furnace and the method of handling the work through the furnace but in general the question of power concerns principally the operation of auxiliaries and continuous or intermittent demands for power will influence the choice. Electric and steam power are well adapted to continuous operation. Steam power, due to condensation, is not well adapted to an intermittent demand. Electric, air and hydraulic power are adapted to intermittent operation where the energy may be stored during certain parts of an operating cycle. Electric power is gradually superseding air and hydraulic power in steel mill practice.

In considering the human element, intelligence may be purchased but without skill has potential value only, skill may be required but without intelligence will accomplish indifferent results. Morale must be developed; labor has in a large measure lost that sense of fidelity and loyalty to the ideals of a trade that forms a basic morale. This question must be solved in each plant depending upon the type of organization, the distribution of responsibility and the sequence of authority are large factors in determining the most effective form of co-operation.

Recent and to some extent present conditions show that while the working conditions within the plant may be of the best, if the workman has no suitable place to live, his value as a producer is greatly diminished and the type of workman is directly reflected by his home surroundings. The cheap lodging house or bunk house under unsanitary conditions reduces the type of labor to that of the floater, unskilled, of low intelligence and often a menace morally as well as physically to the community. Sanitary conditions mean health, self-respect and increase in the morale. These conditions have been studied in connection with the "safety first" movement leading to a more technical study of occupational disability.

The following conditions are quite common in connection with furnace installations; high temperatures, humidity, noise, vibration, insufficient illumination, excessively bright or harmful industrial lights, vitiated fume or dust laden air. While heat is fundamentally apart of the subject considered, every effort should be made to lessen its ill effects and to prevent its radiation. To some extent this may be attained by the use of heavy, well insulated furnace construction, water-cooled or insulated doors, protective shields or screens and a natural circulation of air due to locating the furnaces away from walls and by placing them in the center of the building. Ventilation may be improved by a forced air blast directed from the walls and windows to the center of the building.

In connection with the application of heat in industrial furnaces, maintenance of structure and production requires considerable study. In order to reduce the shutdown or time that an appliance is out of service, it is desirable to use standardized units as far as possible, to keep sufficient spare parts on hand and to use standard material in construction. Simplicity of construction is the first requisite and in furnace work the use of standard brick shapes and the avoidance of special tile should be considered. The value of standardization

is not fully appreciated. For instance, a consulting engineer bought for export one each of three different makes of melting furnace.

Watch the Operator.

Fume, smoke, dust, dirt, etc., have a direct injurious effect in causing discomfort to the operator, decreasing the productive ability, and resulting in the general lowering of the resistance to disease. When these elements are ejected outside the plant, the surrounding neighborhood suffers injury. Fume and dust from certain chemical and metallurgical operations, smoke from furnaces or boiler plants, noise from hammer shop, have an injurious effect on the neighborhool and eventually affect its character, sometimes leading to a warfare in which the neighborhood or industry is a victim, the neighborhood is lowered in character or the plant moves.

Some of the conditions outlined above are controlled by restrictions. These restrictions may be legal as by municipal ordinance, state or federal enactment; or the result of a mutual contractual relationship as that with insurance companies; or the restrictions may be moral as imposed by the general civic sense or industrial conscience. Legal restrictions are most direct in their deterrent effect providing, as they do, a penalty for non-observance, at the same time they are very apt to be below the actual needs as indicated by public policy.

Accident and fire hazards may be minimized by the observance of accepted principles of safety engineering and may be covered in part by insurance governing the hazard peculiar to the use of certain forms of heat energy, such as the method of storage, the quantity stored, method of handling, and the way in which it is used. One of the older principles of fire protection was that fires cannot be prevented but they can be controlled and stopped; the newer idea is not only fire protection but more insistently fire prevention.

Failure of energy supply apart from accident, is due largely to transportation troubles and to labor troubles which may interrupt either production or transportation. Such interruption may be reasonably guarded against by providing proper storage. In some cases the user must provide for these contingencies while in others the producer does so by providing local storage. The exhaustion of one source of fuel may require a change to another fuel, or conservation may demand a seasonal distribution or restriction in favor of certain classes of users, as with the natural gas supply in Pittsburgh.

As furnace operations differ widely in the fuel and in the method of utilizing it, the capital cost or investment in any proposed combination of furnace and fuel should be carefully estimated as it may be found that the cost of furnaces with their auxiliary equipment and handling devices and the cost of fuel storage for any particular fuel does not give the return in earning capacity that another combination of equipment and fuel would give, or when the same floor space is devoted to productive use and the heat energy purchased. The amount of capital which may be tied up in this manner and the real estate occupied as well as the cost of operating a fuel storage plant, not only affects the cost of the fuel used but must be balanced against the potential possibility of utilizing the land and capital as well as a corresponding amount of expense in productive operations. In the same way the fixed charges on floor space, equipment and material must be considered in connection with the investment required and balanced against the potential earning capacity of a different combination of these items.

With a given quality of product and given production facilities, the cost of the finished product will result from the rate of production and the cost of operation. The rate of production will depend upon the output and the hours of operation per day or other unit of time. Output and rate of production will govern the selection of a furnace equipment, the method of heating, the method of handling and the method of cooling. These in turn are influenced by the efficiency of the operatives. There are no fixed standards to determine definitely the form of equipment or fuel to use. Both must be selected with regard to the manufacturing requirement and the plant conditions. Fuel and equipment should be selected for what it can do under specific conditions.

Definite Checks.

Output per unit of floor space per operative or per unit of fuel are definite checks on the manufacturing conditions. Cost per unit of fuel or per unit of output is not determinative, and the real question is: What does it cost to do things? which in this case is to produce a quality product at minimum cost. The cost of operation will depend not only on the cost of the raw material but should include that incidental to the process. The manufacturer does not control the price of fuel but he can to a great extent control the quantity used by the selection of a furnace and fuel adapted to his individual plant conditions. The amount of fuel used will depend on the design of furnace, nature of the operation, and the operation of the furnace. The design of the furnace has its greatest influence on the amount of fuel used in production while the nature of the operation largely influences the amount of fuel used in starting and stand-by operation.

In considering the fuel cost too much emphasis has been laid on the heat value of the fuel, its combustion and the generation of heat, and too little attention has been given to its proper utilization. Many absurd comparisons are made between different fuels, based merely on their heat content, but it should be noted that while a change in the form of energy increases the unit cost of the energy it does not necessarily increase the cost of the ultimate result sought. The ultimate cost is largely influenced by the method of utilizing the energy in its new form.

To reduce labor costs means necessarily increasing the productiveness of the worker. High wages may or may not tend to reduce labor cost; reduction of working hours may or may not reduce labor cost. Labor turnover is influenced largely by the location of the plant.

The use of power is usually considered as an expense. The power required in industrial heating operations is for the most part used in driving the auxiliaries and in handling the work to and from the furnace. Where furnaces are operated with the air for combustion applied by a power-driven unit, the cost of the power is often regarded as a unnecessary expense when compared with stack or natural draft. It will usually be found, however, that the better control of the heating operation both in time and uniform heating condition more than justifies the cost of the power used.

This same idea would hold in providing for the generous use of power in the operation of auxiliaries, in the reduction of manual labor and more particularly in handling the quenching medium. In many cases atmospheric cooling the quenching medium is sufficient to maintain the temperature within the required limits, while in other cases the volume of the output and rate of production requires the installation of a more effective cooling system, which in turn may mean a refrigerating plant. Charging and discharging machines, conveyors and quenching devices represent justified outlay for power.

Rejected Material.

Rejected material is not only a direct loss, represented by the raw material, labor, power and fuel costs, but reduces the productive capacity of a plant. Rejected material may be due to defective raw material; sometimes to poor design where the piece is ill-adapted to the treatment proposed, that is while the piece may be treated individually with fair success, by its shape or form it does not lend itself to mass production.

Imperfect heating, due to an overloaded furnace or to improper preliminary or previous treatment, is a common cause for rejected material. The barbarities of the forge shop sometimes

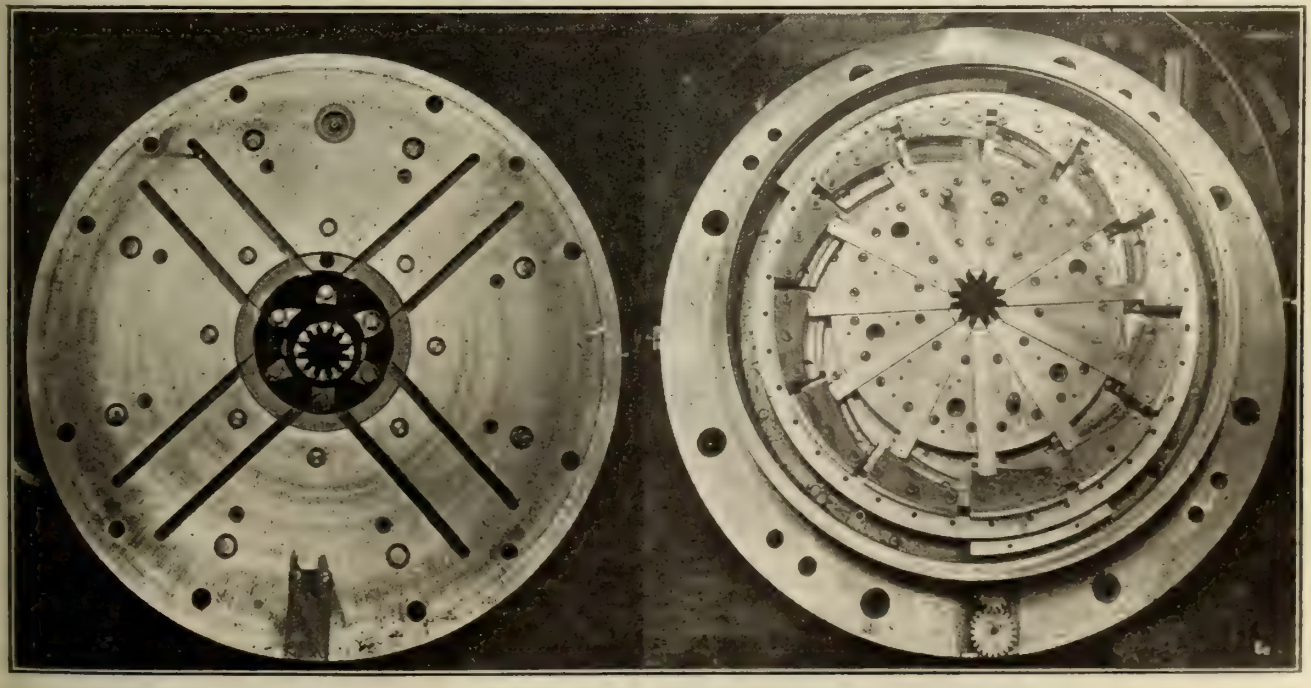
A Multiple Gear Shaper of Interesting Design

The Stevenson Gear Company, of Indianapolis, Indiana, have recently developed a new and improved type of gear cutting machine known as the Stevenson Multiple Shaper. This machine differs from the usual type of gear cutting machines in that it cuts all or a multiple number of teeth in a gear or similar product at one operation



The essential member of the machine is a special tool head which consists primarily of a series of radially disposed tools spaced about the circumference of the blank to be cut. The machine operates in the same manner as an ordinary vertical shaper, except that the tools are held stationary and the gear blank is reciprocated past the tools. The mechanism consists essentially of a ram carrying a blank supporting arbor and the multiple tooled head for operating upon the blank. The frame of the machine is a casting of rectangular box section with a vertical cylindrical portion at one end. The ram is mounted in the center of the cylindrical part of the frame, and the tool head is mounted above the ram at the top of this portion. The crank shaft which drives the ram is journaled near the top of the rectangular section and is provided with an adjustable crank head at the end next to the ram and is driven through rack gears by an individual electric motor. The arbor which carries the gear blanks is not made solid with the ram but fits in a socket in a spindle which is journaled inside the ram and is free to rotate independently of the reciprocating motion imparted to it by the ram. An intermittent indexing movement is imparted to the spindle after each cutting stroke by an intermittent gear train. The machine is seven feet high, weighs 17,000 pounds and when operating to full capacity is driven by a 100 H.P. motor. Its capacity is for gears 12 inches in diameter, 6 inch face, 4 diametral pitch.

Tool Head.

The tool head consists of a flat, steel disc 3 feet in diameter, provided with a hole at the center and a number of radial grooves cut in its face in which the tool bits are arranged like the spokes of a wheel about the circumference of the gear. Successive feeding movements are imparted to the tools by an annular sectional cam ring. As the gear blank is reciprocated past the cutting tools, the tools are gradually fed in by successive cuts to the full depth of the tooth. At the completion of each stroke of the ram and before the next cut begins, the gear blank is indexed a space equal to one tooth, thereby presenting a different tool to each tooth from the one which made the previous cut. After the tools have been fed in to full depth, they are held stationary in that position while the cutting process continues until the gear has indexed one complete revolution, thereby giving each tool an opportunity to take one last cut on each tooth. This final complete index insures a uniformity of spacing of the teeth in the gear equal to that of the indexing mechanism. Uniformity of the tooth form is secured even though the tools themselves may be far from uniform for it is at once apparent that if any tool is longer or wider than any other tool, even though it be only a thousandth of an inch, that portion of it which is longer or wider will take one last cut on the corresponding portion of each tooth in the gear, thereby eliminating any variation which may have been caused by previous cuts. By this process of finishing all the teeth of a gear with a single finishing tool, the machine is said to attain great accuracy and the speed is multiplied by the number of tools operating on the gear blank at one time.

To technical men the most interesting individual mechanism on this machine is the tool head, as it involves the solution of the most interesting and important problems, both in design and construction. In the three illustrations of the tool head, Fig. 1 is a top view of the tool head as it would appear when in operation on the machine. Fig. 2 shows the tool head partly disassembled and shows the principal details of the mechanism. When it is mounted on the machine, the only working parts to be seen are the points of the tool bits

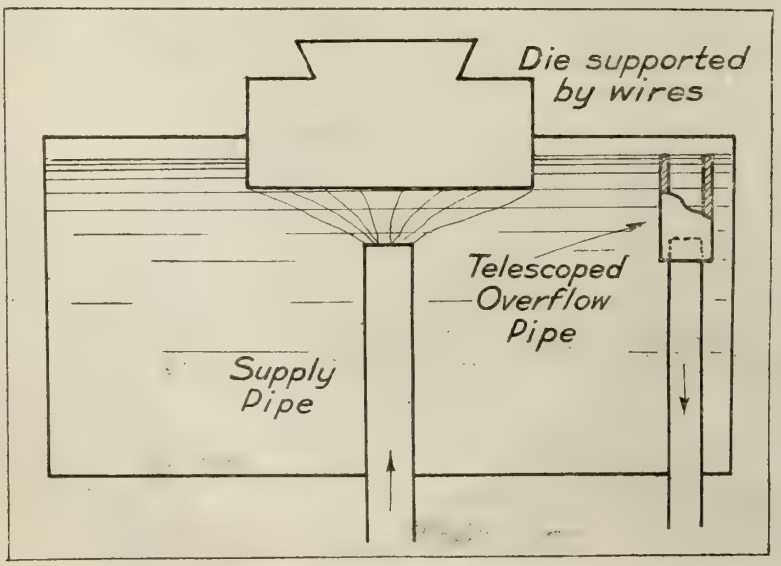
WHAT OUR READERS THINK AND DO

HARDENING DROP FORGING DIES.

By P. W. PEEL.



When hardening drop forging dies, it is very essential that some type of furnace which heats evenly be used. Do not heat too fast or the corners and light sections will be overheated and weakened.

If large pieces of steel are placed in a furnace and allowed to remain exposed to the direct heat and to the air therein, their surfaces are likely to become oxidised. Since the faces and walls of the impressions must be hardened, it is desirable to afford protection to them. This is sometimes done by placing a quantity of granulated charcoal in the furnace on the hearth and laying the die face downward. A more satisfactory method however, consists in placing one or two inches of granulated, charred leather in the bottom of a shallow hardening box and laying the face of the die on the leather, the box being packed with leather. The die may then remain in the furnace until it is uniformly heated throughout; the corners at the base of the tang of die being filled with fine clay to prevent unequal heating. In this connection I cannot too strongly emphasize the necessity for making accurate pyrometric observations, not to ascertain furnace temperature, but to check the material under treatment.

The form of bath depends on the character of the pieces to be hardened, one satisfactory form being shown in the accompanying sketch, having the die resting upon supporting wires. The overflow pipe should be telescoped, thus enabling the operator to regulate the depth of water in the tank. To obviate tang distortion it is advisable to quench this portion first; the same being accomplished by fixing the die on the wires, tang down, and allowing the water supply to play thereon. The die should be left in this position until the tang is cooled below a red heat, then being turned and the supply stream played against the face until cooled.

To prevent the tang from softening before the face becomes hard, turn water by means of a dipper, on to the tang until red has disappeared from the face then cease pouring on to the tang and allow heat to work from the centre of the block up through the tang, which will in all probability be reheated to low red. After the block has cooled should be placed over a fire and re-heated to remove hardening strains.

At times it is necessary to harden die having slender projections or some weak portion which is likely to crack during the process, cracking resulting from unequal contraction which can be avoided by rubbing soap on the projection, more especially at the junction the die.

Showing method of hardening the dies.

IDEAS WANTED.

We are particularly desirous of obtaining for this section of our journal, short instructive ideas. These can cover any phase of machine shop practice and should be illustrated if possible by a sketch of the idea being described.

If you are unable to make a neat sketch, do not let that stop you. Draw the idea as best you can, send it in to us and we will finish it up for you. For all accepted material we pay a good rate, so that not only do you help some one else by passing along the idea, but you benefit yourself as well.

This section should be a regular exchange of ideas. Surely Canadian mechanics have many schemes that have saved them both time and money. Send them to the Editor of Canadian Machinery, 143 University Ave., Toronto, Canada. Don't be a once in a while contributor. Become a regular. You'll find it pays.

SPEEDING UP SHOP TRUCKS.

To reach certain overhead stora racks at the plant of the Richards W cox Manufacturing Company, it w necessary to employ a short ladd which, if left where it was used—a this often happened—blocked an ais

This difficulty, continues "Factor was met by hinging the top of the l der to the framework of the overhe rack and attaching the bottom of t ladder to a weighted rope passi through an overhead pulley. If a tr is brought past while the ladder is use, it is a simple matter for the tr operator to release the counterwei so the ladder will rise up out of the w The worker using the ladder revol it to position when he is ready. Wh not in use the ladder is always held out of the way.

3225. **Corrugated Iron Sheets.** Liverpool firm desire catalogues, prices of corrugated iron sheets, gauges from 24 to 32, size 6 feet b feet by 8/3 inches, for export to Gold Coast, West Africa.

DEVELOPMENTS IN SHOP EQUIPMENT

MARKING MACHINE.

Noble & Westbrooke Mfg. Co., Hartford, Conn., have recently placed a machine on the market which is said to perform graduating operations with speed and accuracy. Hand and power feed machines are both made and on the power-driven machine; the loading and removing of pieces of work on the machine are the only duties required by the operator. With the hand machine, one turn of the handle completes the work. Provision is made for holding the work in the proper relation to the graduating die, and the depth of the marking is governed by means of a foot-lever cam, and weight, which are governed by a positive stop that is adjustable to provide for making any desired depth of lines. This insures making even and accurate impressions.

The machine is equipped with steel spindles, adjustable bearings, and is fully automatic in operation, being stopped by means of a clutch on the spindle which drives the marking die. Practically all types of modern machine tools are equipped with micrometer adjustments, and this machine is well adapted for the graduation of the dials used on micrometer adjusting screws; it is also adapted for graduating and numbering cross-slides and compound rests for lathes.The graduating and numbering are completed in one operation. This company also furnishes the full equipment for these machines, including the engraved steel marking dies.

ADJUSTABLE SHELL REAMER

The Cleveland Cutter and Reamer Company, of Cleveland, Ohio, has placed on the market a new type of inserted-tooth adjustable shell reamer, where the backs of the blades are provided with serrugations placed at an angle and fitting corresponding grooves in the slots in the body. The construction permits of a double adjustment, the lock nuts providing an adjustment of 0.083 inch, while moving from one corrugation to the other provides a similar adjustment, and this action of sizing can be continued until the blades are worn out. The reamers can be furnished either with straight or helical placed blades. The standard sizes range from one to six inches in diameter, but any size may be made for special requirements.

SURFACING MACHINE

The Peerless Surfacing Machine Company, of Troy, New York, has developed what will be known as the "Junior" surfacing machine, which will be used for the surfacing of small work. The abrasive belt is carried on two small pulleys located in a swinging bracket at one side of the machine. This arm can be clamped in any desired position, and likewise the rest for carrying the work. The machine is of the bench type and may be transported to any part of the shop and mounted in different ways. It may be driven direct by motor or by using a countershaft. The opposite end of the machine spindle may be utilized for a small grinding wheel or disc plate. The machine is adaptable to a large variety of work.

MILLING AND GRINDING ATTACHMENT

A combination milling and grinding attachment has recently been placed on the market by the A. F. Robbins Company, of Waltham, Mass. It is especially adapted for use on small lathes for milling or grinding operations without removing the work from the machine. The base attaches to the tool rest of the lathe and the head can be swung to any angle by means of a swivel bolt in the centre and secured by means of a quick acting clamp. A graduated circle facilitates locating. The spindle bracket may be adjusted horizontally on a vertical slide and may be set very accurately to thousandths of an inch. By the use of different spindles the range of operations is very large. Provision is also made for supporting the outer end of the arbor when desired.

3226. Saws.—A Liverpool firm desire catalogues and prices of pit saws complete with fittings 6 feet, 7 feet, and 8 feet. and cross-cut saws of the same size, for export to the Gold Coast, West Africa.

Investigating Heating Furnaces

THE University of Illinois, which has done some valuable work through the medium of its Engineering Experiment Station, is now engaged on an investigation of the hot air furnace and system of heating. This is being carried out in co-operation with the National Warm Air Heating and Ventilating Association, and should be productive of good results. In order that the results obtained from the experiments should be of use in practical problems, a plant has been built which operates under the exact conditions found in the ordinary hot air heating installation. The objects of the experiments are to determine a proper method of rating hot air furnaces, so that the proper size of furnace can be definitely selected for the service required, to determine methods of increasing the efficiency and capacity of furnace heating equipment, and generally to determine all unknown factors in connection with this type of heating plant.

There is no country in the world where more interest should be taken in domestic heating plants than in Canada, where they are very much in evidence for the greater part of the year, and where the house holder has to go deep into his bank account every year, to purchase indifferent coal which he feeds to an inefficient furnace. Then if the weather gets really cold with a high wind he shivers anyway. We have never been in a house in this country in the middle of winter yet that was comfortable, and whether this was due to the bad building or the poor heating system, or both, the effect was the same.

Most hot air furnaces are put into houses in a happy-go-lucky spirit, and very often they are cut down by the contractor as small as he possibly can, in order to save a bit more money. The actual requirements from a scientific point of view we do not believe are ever considered. The result is a gross waste of fuel, without any degree of comfort, and if the experiments now going on can determine an absolutely correct way of determining the capacity of furnace required, and also a method of rating which will ensure the purchaser getting that capacity, the benefit to the people in general will be enormous. If in addition to this, the most efficient way of carrying piping from basement to rooms, the correct position of register, and the right type of insulation are determined, there will be a large saving in fuel consumption, and the money thus saved to the country will be available for investment in Canada, instead of being eaten up by U. S. exchange and freight charges.

The house heating plant in its individual capacity may not look much, but multiplied by the hundreds of thousands of families that use them, it is an exceedingly large factor in the country's expenditure. When we consider that of the money spent thus for fuel, the householder gets probably 20 per cent. of its value in heat, he should be interested in anything that tends to improve matters along these lines.

A Vision Worth While

THE WORLD is used to turning to the United States for stupendous undertakings, and not in vain, for while they do not always get the best, yet they usually have the biggest of everything. In another part of this issue will be found an account of the mammoth bridge which is being erected across the River Hudson, to form a great artery of commerce between the states of New York and New Jersey. The bridge like other bridges over the Hudson and East Rivers will be of the suspended type. It would no doubt interest greatly some of the ancient bridge builders of the far east, who in the dawn of the world swung their gossamer like structures on fibre cables over the gorges of the Himalayas, for they would see a structure, surpassing in dimensions anything that their wildest vision could have conjured up, and yet based on the principle that they themselves had used.

We say surpassing anything their vision could conjure, but it is by virtue of that very vision that all these modern wonders have been made a possibility. The bridge builder challenged by the necessity of the times, and aided by the scientist who with infinite patience pursued the jealously guarded secrets of nature, saw in his mind's eye something larger than had ever been attempted, and with confidence in his ability and the material he had to work with, proceeded to make his vision a material fact. So from the crazy fibre bridge swinging above the abyss, and capable of supporting but one person at a time, we have come to the bridge that can carry foot passengers, wheeled vehicles, street cars, and railway trains with perfect safety. Each great bridge as it has been projected, has been a source of wonder to its generation. The Tay Bridge, the Forth Bridge, the first Brooklyn Bridge and latterly the Quebec Bridge with its tragic history, have all caused those of little faith and less vision to remark "it can't be done."

Science , the handmaiden of industry, goes quietly on with her appointed task, and makes available better and better materials, which give added strength with less weight, and make it possible for the builder to plan bigger and bigger things . It is all a matter of vision. The scientist, who projects his mind into the abstract; the engineer who takes the result of the scientist's researches and applies them to practical use, and the capitalist, who from his faith in the engineer and scientist, gathers together the gold to make these visions possible, knowing well that though he stands for great reward he may well stand to lose all. So science, industry, and capital go forward hand in hand, linking up town and country state and nation till the day will come when all the world will be joined up with such arteries that the farthest points apart will be reckoned not in weeks, or days, but in hours.

MARKET DEVELOPMENTS

Buyers Keep Up Bombardment for Lower Prices

Machine Tool Business is Dull—Several Reductions Are Made in Price of Small Tools—Dealers Are Sometimes Selling Below What It Costs to Stock Material in First Place.

MARKET conditions are not undergoing any marked changes. Business in machine tools is dull and dealers are not afraid to admit it—but then it's summer, and business was never any too good at this season. Nearly all dealers are receiving notices from their principals that there are reductions being made in the prices, and some makers of foundry equipment are out with new prices.

There have been several reductions in the prices of small tools recently. High speed reamers are down about 20 per cent, while milling cutters have suffered a reduction of 10 per cent. High speed drills are also down, the decrease being all the way from 10 per cent on the smaller sizes up to 30 per cent. on the larger drills. Carbon drills are now selling at 50 per cent. off list.

Pittsburgh reports that the increase in demand upon the steel mills has spread during the past week. The improvement started with sheets and has spread to other lines. Further improvement is looked for, but nothing of a sensational character.

The wages of common labor among the independents has come down to the 30 per cent. rate. In fact in the east it is down in some cases to 25 and 27 cents. The steel corporation is still paying the 37 cent rate.

The scrap market situation is about as bad as it ever will be. In some districts low stocks point toward an early improvement but the old policy of buying for immediate requirements continues.

Several independents are openly quoting 1.75c on bars and 1.85c on shapes, and plates instead of quoting such prices as representing a special concession to a particular buyer. Wire products and standard steel pipe are quite well held at prices which developed early in July.

STEEL INDUSTRY IS NOW RECOVERING FROM SEVEREST PART OF DEPRESSION

Special to CANADIAN MACHINERY.

PITTSBURGH, August 4—The increase in demand upon the steel mills, noted first in the report of two weeks ago, has spread in the past week. The improvement began with sheets, which have shown the most marked increase in mill demand, and has clearly extended to merchant bars and tubular products, while there is some increase in other lines. In no steel mill product has there been any decrease in demand in the past fortnight.

It would be quite unsafe to base any high hopes on the improvement that has begun, even though the improvement is practically certain to proceed farther in the next few weeks. The point is that this is not a broadening in the ultimate consumption of steel, but is in the direction of demand upon the steel mills returning towards a normal relation with the actual ultimate consumption. Of late the demand on the mills has been subnormal, by reason of the existence of stocks which the holders desired to liquidate. These stocks were of steel in the hands of jobbers and manufacturing consumers and manufactured wares of various sorts in the hands of manufacturing consumers, hardware, machinery, cutlery, tools, agricultural implements, etc. Demand upon the mills was at one time less than 20 per cent of capacity, perhaps only about 15 per cent, and it is obvious that even in times of lowest industrial activity the requirements in steel could not run at so low a rate. To illustrate the point, freight ton-mileage movement on the railroads, which is certainly an index of general industrial activity, has been running only a few per cent below the rate in the best year before the war, whereas if steel demand were 20 per cent of the present capacity, and it has been less than that, it would represent less than one-third of the steel output in the period from which freight movement shows only a few per cent falling off.

Again, debits to depositors' accounts at banks, volume of business in the country, have been running only about 20 to 30 per cent below the amounts a year ago, while steel production lately has shrunk by about three-fourths, being only about one-fourth as great.

The Process of Liquidation

What is occurring now in demand upon the steel mills is a recovery from the extreme stagnation caused by the necessity of buyers reducing their stocks. They are not reducing to normal, and indeed they are probably below their normal average already. They are trying to reduce to nothing, to get to a position where they will distribute or fabricate steel as fast as they receive it from mills.

Steel mill operations are now about 20 per cent of capacity. When the demand on the mills catches up with the flow of steel and manufactures of steel into consumption the rate will be, perhaps, 40 or 50 per cent. This would occur without there being any improvement in business generally, without the volume of construction work increasing, and without railroad buying increasing. Those things represent favorable developments that will come some time, perhaps soon. Possibly there will not be much improvement in those respects before next spring. The majority of men seem to think next spring is about the best time to predict. But the steel industry is now recovering from the severest part of its depression.

The character of the business being placed, when scrutinized in detail, bears out the above analysis, and indicates that it is entirely reasonable to expect continued improvement, though at a very moderate pace. Practically all the business received, in the form of strictly new orders and in specifications against contracts, the latter being the form in which the Steel Corporation now gets most of its shipping orders, is for the quickest shipment possible, and the mills are showing a remarkable showing in this respect, often shipping an order a day or two after its receipt. The specifications are quite miscellaneous in

many cases, indicating that buyers wish to piece out with remaining stocks they have.

Steel Prices

The buying does not represent "confidence" in the steel market on the part of buyers. It represents confidence that they can distribute the steel ordered, or manufacture it and distribute the wares made from it, and get their money before anything serious happens in the matter of prices. Men are not buying ahead, but are buying against the business they know they can put through and complete. Confidence in the future of prices is not needed. The buyers may expect lower prices in future, and in fact most of them do, and if prices decline some more then the next order or the order after the next will be at the lower prices.

However, if steel prices are going to decline in future, they will not decline as rapidly in the next few weeks as they have in the past few weeks. The pace of decline will be reduced. Very roughly speaking, it may be said that steel prices on a general average have been going down at the rate of less than a dollar a ton a week, and that is nothing for buyers to be afraid of when they are simply doing prompt business. There will be no "breaks" in steel prices. The market is too soft to break, and there is not enough room left.

Several independents are openly quoting 1.75c on bars and 1.85c on shapes and plates instead of quoting such prices as representing a special concession to a particular buyer. The decline from prices announced a month ago is $3 per ton. Black sheets are down $5 a ton in the month to 3.25c, and galvanized the same amount to 4.25c. In all these products a particularly attractive order would probably draw a special concession but only a small one compared with the way mills have shaded the nominal prices in the past few months. Wire products and standard steel pipe are quite well held at prices developed early in July.

Wages

Practically the last of the independent steel mills have now come down to the 30-cent rate for common labor, a rate that appeared at some mills weeks ago, while in the east lower rates, down to 27, and even 25 cents or even less, are being paid, the east having been in the habit of paying somewhat lower rates than the central west in times of stress. The Steel Corporation is now alone in paying the 37-cent rate. The top rate was 46 cents, and that was with time and a half for hours over eight, the overtime payments having at one time or another been discontinued by all mills. The Steel Corporation may reduce in the near future. Effective at the beginning of this week, the Corporation has made its second wage reduction in the Connellsville coke region, the first having been May 16. The new rates are above the independent scale as further reduced July 1.

The valley pig iron market has made a record in the past week, by showing no decline, but possibly that was due to no business being offered. The valley market is quotable at $20.50 for Bessemer, $19 for basic and $19.50 for foundry, f. o.b. valley furnaces. The transportation cost of assembling the raw materials to make a ton of pig, which is coke, ore and limestone, is more than $10, when it was a trifle under $5 before the war. Hence the furnaces insist that freight rates must come down.

POINTS IN WEEK'S MARKETING NOTES

In the iron and steel trades there still exists the hope that things will improve shortly. This in spite of the fact that the last week witnessed a further drop in prices. Many say that the bottom has been reached, and that although no immediate change can be looked for, the market is sure to improve rather than decline further.

Foundry activities are increasing the enquiries for coke. Prices in this commodity have not changed much, and the volume of actual business is not sufficiently large to speak of. Many foundries are inclined to buy on a spot basis rather than on a contract, this holding especially true on the Buffalo market.

Prices on bolts and nuts are very unsettled. The desire to sell is greater than the desire to buy, this causing frequent shading of prices in order to land business. In spite of the recent reduction on steel bars, makers do not seem inclined to make a further formal price reduction, saying that the present steel bar prices were fully anticipated in the reductions that had been made on bolts and nuts.

The demand upon the steel mills has spread within the past week at Pittsburgh. This improvement began with sheets, and has spread to merchant bars and tubular products, although there is a slight increase in other lines. It is expected that this movement will become better as time goes on.

Several independents are openly quoting 1.75c on bars and 1.85c on shapes and plates, instead of quoting such prices as representing a special concession to a particular buyer. The decline from prices announced a month ago is $3 per ton. Black sheets are down $5 a ton in the month to $3.25, and galvanized the same amount to $4.25. Even at these prices, a particularly attractive order would probably draw out a special concession.

Practically all the independents are now paying the 30 cent rate for common labor. In the east as low as 27 and 25 cents is being paid. The steel corporation is now alone in the 37 cent rate.

Pig Iron Market

Some sellers report a slight improvement in the pig iron market in Chicago. Such business however is mostly confined to carload lots.

The hand to mouth policy of buying is beginning to make itself felt in the New York Market. Foundrymen are experiencing some difficulty in obtaining material as promptly as they require it, owing to reduced production and depleted stocks. Dealers expect a buying movement in the near future, although heavy buying is not looked for. Inquiries are more numerous at present, and it looks as if the turn has been reached.

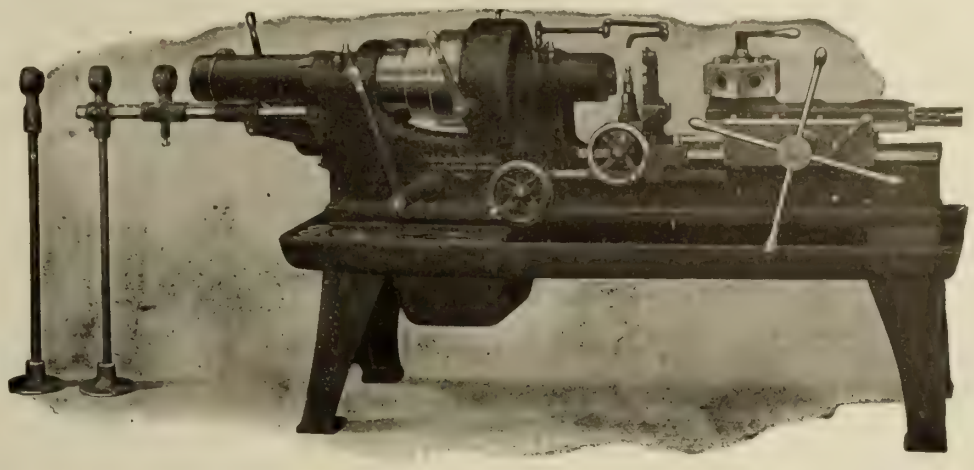
There is a feeling of optimism in the Buffalo market. Again it is a depletion of stocks, that causes the change, and in this case it is expected that one combination will blow in a furnace shortly. If they don't they will have to buy iron elsewhere, and such a step is not looked for yet. The present prices are by no means attractive, and this fact alone makes the above step seem sure. The necessity of filling orders on old contracts has practically forced one producer out of the market so far as new business is concerned. Taken in all there is cause for the belief that things will be better in the district.

Cleveland thinks that prices, as they exist at present, cannot possibly go lower. Some of the furnaces in the district state that $20 for foundry iron is as low as it will go at present. The volume of business being done is very light and whenever orders do come in they are for immediate needs only.

Scrap Metal Market

In Pittsburgh no material change can be reported. If anything, the market is somewhat firmer, and this is said to be due to the tendency of railroads and other producers to hold rather than sell at the present low prices.

A few deals of decent proportions are recorded in Chicago, and the various railroads are offering a fair amount of material for sale, although the market as a whole cannot be said to be brisk. The prices still remain low and lack of confidence in the present quotations seems to be holding buyers out of the market.



In New York, the dealers believe that prices have reached the low mark, and will stay there for some little time. No further drop is expected, and apart from one or two half decent orders the market moves along in the slow fashion it has been accustomed to for some time past.

It is not expected that the demand for scrap will improve in Buffalo for some time as a large majority of foundries have sufficient material on hand to supply their requirements for at least a month or two. Prices are being shaded somewhat by yard interests in the hopes of stimulating interest.

Warner & Swasey Screw Machines

Buying a Pig in a Poke

The buying of advertising space used to be buying "a pig in a poke." The quantity and quality of circulation was shrouded in mystery and often the bag was tied against investigation.

That day has passed. The advertiser no longer depends upon "mere claims." The Audit Bureau of Circulations has untied the strings to the sack and the circulation of the better class of publications is thrown open for the most searching scrutiny.

In buying advertising space in the Canadian Machinery you are not buying "a pig in a poke." Our A. B. C. statements will stand the analysis of the most exacting investigator.

BUYERS ARE VERY MUCH IN CONTROL OF MARKET IN TORONTO STEEL TRADE

Special to CANADIAN MACHINERY.

TORONTO—The summer season was never famous as a time to sell machine tools, nor is this summer any exception to the rule. Dealers admit that business is dull, but at the same time they admit they are selling a few tools here and there.

But there are none of the large sales being made that the dealers like to get hold of. Existing plants are not making extensions to their plants or equipment, nor are there any new firms that are outfitting plants with a view to going into the manufacture of some new article.

It might be thought that under such circumstances there would be a number of failures, and that a number of plants would be thrown on the market for disposal. Such is not the case, however, and when Canadian Machinery inquired regarding this, the manager of one of the largest firms handling used and rebuilt equipment answered that his firm had taken in only one plant during recent months. "One might imagine that in such a season there would be quite a lot of material offering in the way of used equipment, but it speaks pretty well for the standing of these places that there should be practically nothing to indicate that there are shops at the point where they have to shut the doors and dispose of any portion of their equipment."

Most of the dealers are getting notices from their principals that there are reductions being made in the prices of machine tools of various sorts. Some makers of foundry equipment are out at present with new prices, and one maker of drills also sent notice this week of a reduction. Makers are apparently convinced that reductions will not bring them any business, and these new prices are put out as feelers. Of course many of the makers state that their manufacturing costs are less now, and they are able to offer a better price, but lower costs must be more than offset by the fact that there are very few machines being made, and the overhead assessed to each one must necessarily be high as a result.

The Small Tool Market

One of the dealers spoke a very trite thing in regard to prices this week when he admitted "if there were only more business being done there might be more cutting of prices."

There have been several reductions in the prices of small tools in recent weeks. High speed reamers, for instance, have come down about twenty per cent, while milling cutters suffered a reduction of ten per cent. High speed drills are also down, the decrease being all the way from 10 per cent on the smaller sizes up to 30 per cent on the higher sizes, which sell the least.

Carbon drills are now selling at fifty per cent off the list. The firms making drills are anxious to secure orders, and are making concessions to induce the should-be large user to come in now and place business during the slack weeks.

One firm that we heard of got very fair treatment in an unusual case. The company sent out inquiries for several special sizes in fairly large lots, and the prices they received were quite favorable owing to the quantities named in the first place. When it came to actually placing the business the buyer specified against only about one-third the quantity on which the price had been named. He explained that his appropriation had been cut and that he had acted fairly all the way through. The price was allowed to stand on the smaller amounts.

The average order that comes to the dealer in small tools today is a small affair, and the man who is buying is very much in need before he places his orders and so wants to get delivery quickly. It means that the dealer must keep up a very well assorted stock in order to get his share of the small volume of business that is moving.

The Steel Market Slow

Dealers would like to know when the end of the period of liquidation is going to come in their line of business. The United States market is very much disturbed at the moment, and no price schedule seems to posses sufficient stability to withstand the onslaughts of the competitors, or of those who are out to get rid of a lot of material for which they have no further use.

One dealer, who buys a lot in the U. S. market explained that there were such a large number of building programmes being abandoned that stores were being put on the market in order that realization might be made at some price. In this way there are always bargains to be had, and no steel company could hope to meet these prices and stay in business for any length of time.

Selling Very Low Yet

One hears of cases where Toronto dealers are still selling well below what it cost them to stock the material in the first place. As far as we can learn, stocks in local warehouses are being brought down very satisfactorily, and merchants have so far been able to accept their losses safely. Even at best, it is a poor way of doing business, and dealers here realize that the liquidation price, if it continues long enough, is sure to have an effect on the permanent price whenever the market gets in a mood to have such a standard.

Then the purchaser is keeping up a constant bombardment of the market in a quest for lower and still lower prices. Some of the items on which quotations are asked are rather amusing. Apparently there is no limit to the size of an order that is sent the rounds of the dealers in order to secure a figure. Items that in ordinary times would never be subject to quotations are now marched along to the market and loaded up with prices and terms.

All this tends to make it harder for steel merchants to get going along sound business lines.

Then the actual orders that are placed are very small. Boiler tubes are sold in very small lots, plate is not much in demand, while sheets are not moving much better even at the new prices. Some of the dealers profess to have very little confidence in the present sheet market. "There has been too much of a spread between bars and sheets in the past," stated one Toronto dealer, "and I believe that there will be a narrowing down of this gap. There was a great deal of sheet capacity brought into existence in United States during the last two years, and a lot of that must go down. These people are after business, and the thing they are doing is to cut, and they are cutting away the margin between sheets and bars."

Some Orders Coming

Some of the mill representatives are not at all disappointed over the business they are doing. A fair tonnage is going through, and it is pretty well assorted, although the automobile industries are still buying pretty close to their actual needs, and very often in much smaller quantities than usual.

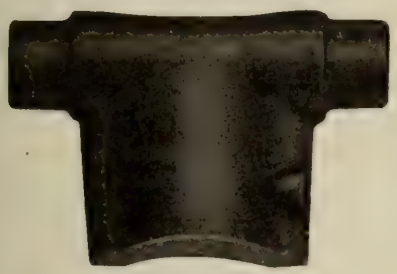
There is a tendency in the steel market to express regret at the attitude of the building trades to take any less pay than they received before. The trade seemed to be of the belief that even yet there might be time to get structural work under way for winter finishing if there were some concessions made.

In the Scrap Market

"All the worst things you have ever said about the scrap market are still true," was the statement of the leading scrap metal yard this week. "There is hardly any business at all, and any concern that is staying in during this period must be pretty well backed. I believe that fully 75 per cent of the dealers are out of business. Many of the smaller ones believe that it is better for them to get out entirely until things take a turn for the better, and no doubt a good many of them will come back when the turn comes. So far, we can see nothing in sight to indicate that there is anything better in store."

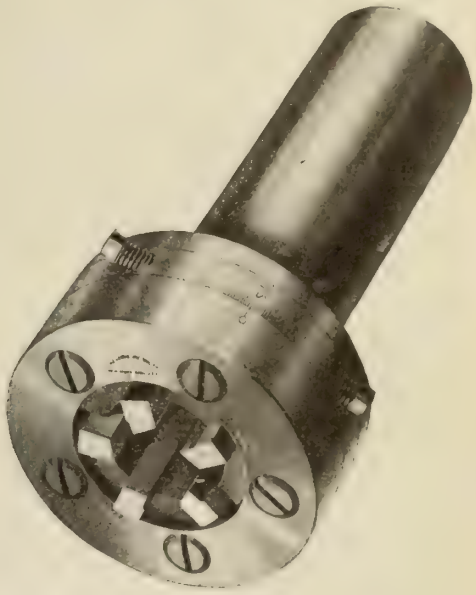
Trade Gossip

The John Bertram & Sons Co. Limited, and Pratt & Whitney Co. of Canada Limited, are closing their plants for two weeks vacation from the 30th of July. Correspondence will be given attention, and orders for goods in stock will be shipped during the vacation period.



The policy of closing plants for summer vacation has been tried out in some large plants in the United States, and some Canadian Companies are making the experiment this summer, and if it proves satisfactory, it will, no doubt, be acted upon annually hereafter.

GEO MET RIC



Right on the Lead

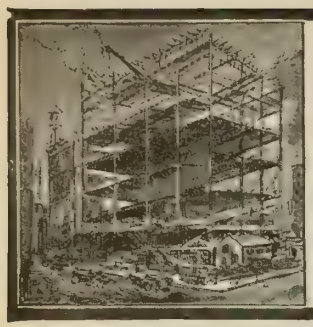
2,000 A DAY

$\frac{1}{16}$" TURNED DOWN ON 2,000 DROP FORGINGS WITH A GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOL

There is an extensive quantity of milling that is done with great economy by the use of GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOLS.

Like all other Geometric Tools, the Hollow Mill is regarded as superior at home and abroad. A Sydney (New South Wales) man volunteers the good information that he has used different styles of GEOMETRIC DIE HEADS and GEOMETRIC HOLLOW MILLS quite a lot, and after cutting threads under all sorts of conditions with all sorts of methods on his side of the world and in England, he has arrived at the conclusion that the GEOMETRIC WAY CANNOT BE EQUALLED.

The Geometric Hollow Mills provide an efficient and economical method of reducing duplicate parts to an exact diameter prior to threading and for brass finishing.



Send for the Geometric Adjustable Hollow Milling Tool Booklet if you are interested, for it tells what these tools are doing.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

HUDSON RIVER BRIDGE WILL BE LARGEST STRUCTURE IN THE WORLD

WHEN completed, the Hudson River Bridge will be the wonder of America, as far as bridges are concerned. Here are some of the more important features and figures in connection with it.

The main outlines of the bridge, as at present determined, call for a total length from anchorage to anchorage of 6,660 ft, this to be divided into two shore spans each 1,710 ft. long, with a central span across the river of 3,240 ft. Including the anchorages the length is 7,460 ft.

A roadway 220 ft wide, will be suspended from four steel cables, each consisting of 80 lines of eyebass arranged in three banks and enclosed in a watertight tubular casing of bronze plating; the diameter of this being 15 ft. The upper deck of the bridge will have a roadway for automobiles and motor trucks, this to be 155 ft. wide in the clear. There will also be a two trolley line track and two 17 ft. walks for passengers. On the lower deck will be ten trunk railway tracks.

If the Olympic; Leviathan; and Aquitania were placed in the center span, there would still be four hundred feet to spare, and although the combined weight of these three vessels is 160,000 tons this would not equal the weight of the main span.The two main towers of the bridge will each be 840 ft. high, this meaning that even the Woolworth building will be overshadowed as the latter is only 792 ft in height.

Naturally the anchorages on such a bridge will be of huge proportions. The engineers at present call for a mass of masonry measuring on its base 400 ft. by 375 ft. wide The top of the anchorage will be 220 ft. above the ground level. On top of each base it is proposed to erect two large office buildings 70 ft. wide, 250 ft. long, and 280 ft. high; thus on the two anchorages there will be four modern office buildings, which will of course contribute considerably to the annual receipts of the bridge.

The structural part of the towers, which carries the load of the cables will not be visible, for externally the the towers will look like solid granite. This stonework will act merely as a covering, but inside this facing will be massive, strongly braced steel towers. The protection to the steel work throughout the construction of the bridge has been planned to such an extent that it is expected that one painting of the towers will be good for at least a decade. The total weight of steel in each tower will be 35,000 tons.

A big feature in the construction is that practically the whole of the bridge will be weatherproof. In other words the steel work will be so completely enclosed with rain and moisture excluding material that the cost of repainting will be reduced to a minimum. It is stated that only 15 per cent of the steel work will be exposed. This feature alone should save at least $500,000 annually, for it would at least cost that amount to repaint the bridge annually.

It is impossible in this space to more than barely touch on some of the figures of construction, but even from the foregoing one can grasp an idea of the magnitude of the task. The cost will be about 110 million dollars, but it is expected that the one bridge will be equal in capacity to twenty tunnels, so that the cost is a secondary consideration.

NEW AUTOMOBILE FACTORY STARTS WORK

Present Plant Is Temporary. Plans Are Made And Site Purchased For Permanent Buildings

The Canadian Automobile Corporation have started factory operations at Lachine, Que., where they have taken over the plant of the Rapid Tool and Machine Co. Ltd. This movement is only temporary as they intend erecting a permanent works at Longueil parish. The car to be produced will be named the Mercury Six.

Some weeks ago the actual assembly of parts was commenced, and those in charge of the factory are G. E. Brennan, and M. H. Potter, formerly engineer and production expert to Stevens-Duryea, the well known United States company.

All the engineers in charge of the factory, which is expected to give employment to about 150 men, have been connected with motor construction for long periods. The directors of the company are F. W. Stewart, vice-president Cluett, Peabody, Co., of Canada, Limited, and an ex-chairman of Montreal section of the Canadian Manufacturers Association, chairman of the board, H. W. Austin, managing director of Perrin Kayser, Ltd., vice-president; J. D. Henderson; D. L. Harrington, president and general manager Rapid Tool and Machine Co., Ltd. M. H. Potter, John MacNaughton, and R. J. M. Cantell, all of Montreal.

The site purchased at Longueuil comprises 163,000 square feet, and the company is contemplating erection in the near future. Arrangements have been made with the Grand Trunk for the building of a siding.

Trade Gossip

Efforts are being made to arrange for a permanent building at the Toronto exhibition to demonstrate and display French products only. The French Government is said to be interested in the proposition and it is expected that the eight exhibition cars which will tour the Dominion, showing French goods, will be stationed at the exhibition this year for the complete period.

Three vessels will be added shortly to the Canadian Government Merchant Marine. The Canadian Pathfinder, recently completed at the former Dominion Shipbuilding plant in Toronto, has taken a trial trip and will be delivered at Montreal. The Canadian Cruiser, a 10,500-ton vessel, was launched last week at the Halifax Shipyards plant by the wife of Premier Murray of Nova Scotia The Canadian Challenger was launched recently at Levis, with Mrs. R. B. Teakle, wife of the General Manager of the Government Merchant Marine, officiating. The Challenger is an oil-burner with 8,350 tons deadweight and a speed of 11 3-4 knots.

ERRATA

In the May 19 issue of Canadian Machinery, we published on Page 58 a notice on the Internal threading tool made by the Jones and Shipman Ltd. Leicester, England. Unfortunately the Canadian office address was left out and it might be well to mention that the tools we spoke of are procurable at the Toronto office 163 King St. E.

Canadian Machinery

EXHIBITION TO BE HELD AT OLYMPIA

The Shipping Engineering and Machinery Exhibition to be held at Olympia from the 7 to the 28 of September is almost entirely British. Unlike the exhibition of 1919, there will not be a central position taken up by the foreigner, as was the case when the Dutch section filled a very prominent part of the hall. The vast expanse of Olympia will this year be given up to a remarkable representation display of what British shiping, shipbuilding and engineering can do. A notable feature will be the exhibits dealing with oil fuel and oil engines for shipping. The only foreign element will be exhibits by one or two American and Scandinavian firms. Already over 270 well-known firms have taken stands, and apart from the purely practical side of the display several striking novelties in shipping auxiliaries will be shown and demonstrated. The strongest section of all will be marine engineering, but special sub-committees, composed of leading men in the industry, will see that representative displays are forthcoming to show what is being done in naval architecture and shipping; marine propulsion (steam, gas, oil, hydraulic, electric), engine and boiler appliances, fittings, fuel; auxiliary machinery and refrigeration; heating and sanitation; passenger accommodation, engine-room stores, packings and jointings; discharge and loading arrangements, cargo gear (steam, hydraulic and electrical); iron and steel; non-ferrous metals; acetylene cutting and welding; transporting machinery, and railway engineering. A special section will be devoted to illustrated lectures on problems of the day that bear on the industries dealt with by the exhibition. The following prominent shipping men are taking an active interest in the preparations at Olympia as honorary vice-presidents: Lord Weir of Eastwood, Sir Archibald Denny, Sir Eustace H. Tennyson d'Eyncourt, M. Inst. C. E., K. C. B. (Director of Naval Construction, the Admiralty; vice-president of the Institute of Naval Architects, and Commander of the French Legion of Honor), Sir Alexander B. W. Kennedy, L. L. D., D. Eng. (past-president of the Inst. C. E., and past-president Inst. M. E.), and Colonel R. Saxton White.

The production of the Nova Scotia Steel Co. has been as follows. In the first half of 1921 the steel plant at Sydney has not operated. Coal totalling 280,825 tons was produced during the six months ending June 30, and 99,121 tons of iron-ore, of which a proportion was sold for overseas delivery. At the Trenton plant during June, 884 tons of bars of various sizes and 124 tons of rivets, pit-spikes, and bolts and nuts were made. During June 61,300 tons of coal and 23,050 tons of iron ore were mined.

The Wahlstrom Chuck

Never Slips

With this Wahlstrom Self-Centering, Automatic Drill Chuck two seconds is all you need to change the operation from drilling to reaming, counterboring, or tapping—and you don't stop the spindle; simply grasp the chuck with one hand and replace the loosened tool with another.

The instant-acting jaws of the Wahlstrom close on the entire shank with a grip that becomes firmer and firmer as the resistance to the tool increases.

Made in two styles. One holds Nos. 1, 2 or 3 Morse Taper Shank Tools—with or without tang. The other is made in three sizes, 15-64 to 1-2 in.; 3-8 to 3-4, and 17-32 to 1 in., thus holding all sizes of straight shank tools from 15-64 to 1 in.

Trade Gossip

According to a statement made by Works Commissioner Harris, of Toronto,the resurfacing of Gerrard St., from Carlaw Ave. to Leslie St. will be undertaken this year.

In the opinion of the British Trade Commissioner in New Zealand, the demand for electrical machinery will soon become very great. To his mind, such machinery will include tramway and lighting plant, agricultural, dairying and household appliances.

A Canadian Steel concern secured $10,000 worth of the $100,000 business, which the Toronto transportation commission placed recently. The balance of the order went to the United States. The material ordered was special track intersections, and the contract calls for delivery prior to September 1.

The Board of Railway Commissioners, Ottawa, have granted the application of the City of Galt for an order directing the Lake Erie and Northern Railway Co. and the Grand River Railway Co. to construct and operate a branch line railway in the southerly limit of the city.

— Norman W. Warren, who for the last six years has occupied the position of western manager of the Dominion Bridge Co., Ltd. in Winnipeg, has been appointed general manager for the whole Dominion, with headquarters in Montreal.

Works and plant that cost over £250,000 have just been established at Newcastle, N. S. W.,by John Lysaght (Australia), Limited, for the manufacture of galvanized iron—the only one of its kind in the state. The site occupies 28 acres; production is 600 tons of galvanized iron per month, and provision has been made for an increase in monthly output to 2,400 tons.

The Algoma Steel Corporation, are rolling a new type of rail as far as Canada is concerned. This style rail has never been produced here before and is known as the 100 pound R. E. Section rail. It was developed some years ago by the rail committee of the American Railway Engineering Association, which is composed primarily of the chief engineers of the various railroads in the United States and Canada. The rail has been manufactured and used in the United States for a few years back, but it was not adopted in Canada until a few months ago, when the C. P. R. decided to take it as their standard. Previously an 85-pound rail had been the C. P. R.'s standard-rail. The C. P. R. placed its first order for these rails with the Algoma Steel Corporation so that this plant is the first Canadian plant to manufacture them.

The American authorities have refused to put an import tax on boots and shoes and other leather products entering the states.

The Ontario Government is planning to build a permanent roadway on Yonge St. between North Toronto and Bond Lake, according to Hon. F. C. Biggs.

Power may be sold by the Sarnia Hydro-electric commission to the St. Clair Tunnel Co. Nothing has been settled as yet, but it looks as if the proposition would go through.

Hon. A. McNab, Minister of Public Works for the province of Saskatchewan, has announced that 7,200 miles of new trunk roads will be built by the Saskatchewan government within the next three years $2,000,500 will be spent this year on such work.

It is expected that the two proposed bridges which will connect the Island of Montreal with St. Anne de Bellevue, and Vandreuil on the mainland will cost a round $1,000,000. At present it is the intention to start this work sometime in the fall.

Australia is a large consumer of galvanized iron, and it is believed that a extensive market for the company's products is assured. Many of the skilled operatives from abroad had necessarily to be imported, and an extensive housing scheme has been inaugurated in connection with the works.

Damage to the extent of several thousand dollars was done at the St. Thomas, Ont., pumping station last week as a result of an unusual heavy rain. Kettle Creek overflowed its banks and flooded the pumping station and adjoining property. The attendants worked in water waist-deep in order to keep the plant in operation. It was impossible to operate either the steam or the electrically-driven pumps, but the gasoline engine-driven pumps were kept running for the 13 hours during which the boiler house was flooded.

The shingle mill of A. J. Waskett Arrowhead B. C. was destroyed by fire recently, the loss being $32,000.

The flood destroyed the stock chlorine of lime, and the officials once issued a warning to citizens to boil all water before drinking. The alum supply was also destroyed although the filtration plant continued to operate with reduced efficiency. Notices to boil the water were placed on bulletin boards throughout the city and in the street-cars and announcements were made from the pulpits. The water undermined the roadway alongside the pumping plant chimney to a depth of 5 ft., and prompt steps had to be taken by the city engineer to save the chimney. Rowboats had to be used in this work.

Catalogues

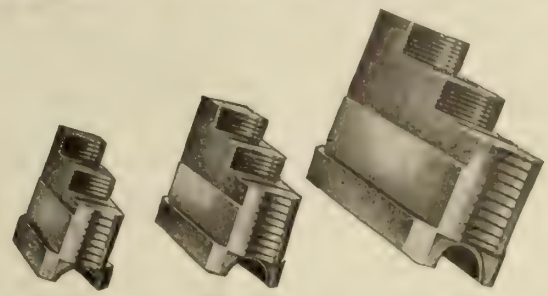
The Geometric Tool Co. New Haven Conn., have issued a small booklet on their "Jarvis" high speed tapping device, and quick changed chucks and collets, also another showing the different style die heads and two illustrations of their machine. The information is condensed form and should be of interest to mechanics generally.

George Ellison, mechanical and electrical engineers at Birmingham, England have forwarded us two catalogues dealing with circuit breakers, and trailing cable sockets and plugs. Both the booklets should interest electrical men especially.

Edwards and Co. Inc New York have issued a new catalogue covering their varied line of electrical signaling apparatus. There is much of interest contained in this book, and it will appeal to purchasing agents especially.

The Westinghouse Electric and Manufacturing Company has just printed Folder 4456 entitled "The Center of Power." This folder illustrates the many uses of the small motor, and encourages the use of labor saving machines in the home, office, shop and farm.

A New Book on Belt Conveyors has just been published by the Canadian Link-Belt Company of Toronto and Montreal. It is known as No. 215, and describes the Uniroll and Multiroll Idlers made by this company. Among the interesting features of the book are:— 1. The correct methods of figuring belt conveyors and the details entering into this. 2. Numerous examples suggesting the correct types of belt conveyors for the handling of bituminous coal, by-product coke, sand and gravel, bagged sugar and similar material, crushed rock, etc.



The Electro Alloys Co. Elyra, Ohio, have issued a booklet on what Thermaloy is, how it is made, and its uses. This material is said to be suitable for galvanizing containers. Annealing boxes, lead, cyanide and salt pots. Retorts, pots and muffles. Pyrometer protection tubes. Furnace grates, rails doors and pneumatic stoker parts. Rolls, chains, link bars, tubes, etc., for continuous operation furnaces, and molds for die casting metals.

Other uses are :—Piercing tips, extrusion and drawing dies for metal tubing manufactures, bars, points, supports, etc., for enameling furnaces. Dies, mold and piercing tips for glass-making machinery. Stirring arms for gas producers and metallurgical roasting furnaces. Retorts for cracking and distillation of oil, and containers for baking carbon products. Communication should be sent to 1692 Glenmont Rd. Cleveland Ohio

THE
TRADE K—T MARK
FOUNDRY
GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

STAYBOLT TAPS

The Better the Man, the More He Appreciates Them—

Not only good when new, but heat treated and seasoned to maintain this goodness. Can be ground on face of cutting edge without affecting their size. That's why you'll find Pratt and Whitney Stay Bolt Taps on the job long after cheaper, "just as good" tools are buried in the scrap pile.

Threads accurately and cleanly cut, with the least expenditure of time and effort, are other reasons why these better Taps are favorites in the shop.

If you've used them before, you know just how good they are. If you haven't, send us your first order—we know you'll be back for more. They're carried in stock in our sales rooms in all large cities.

"Planting" Another Milestone

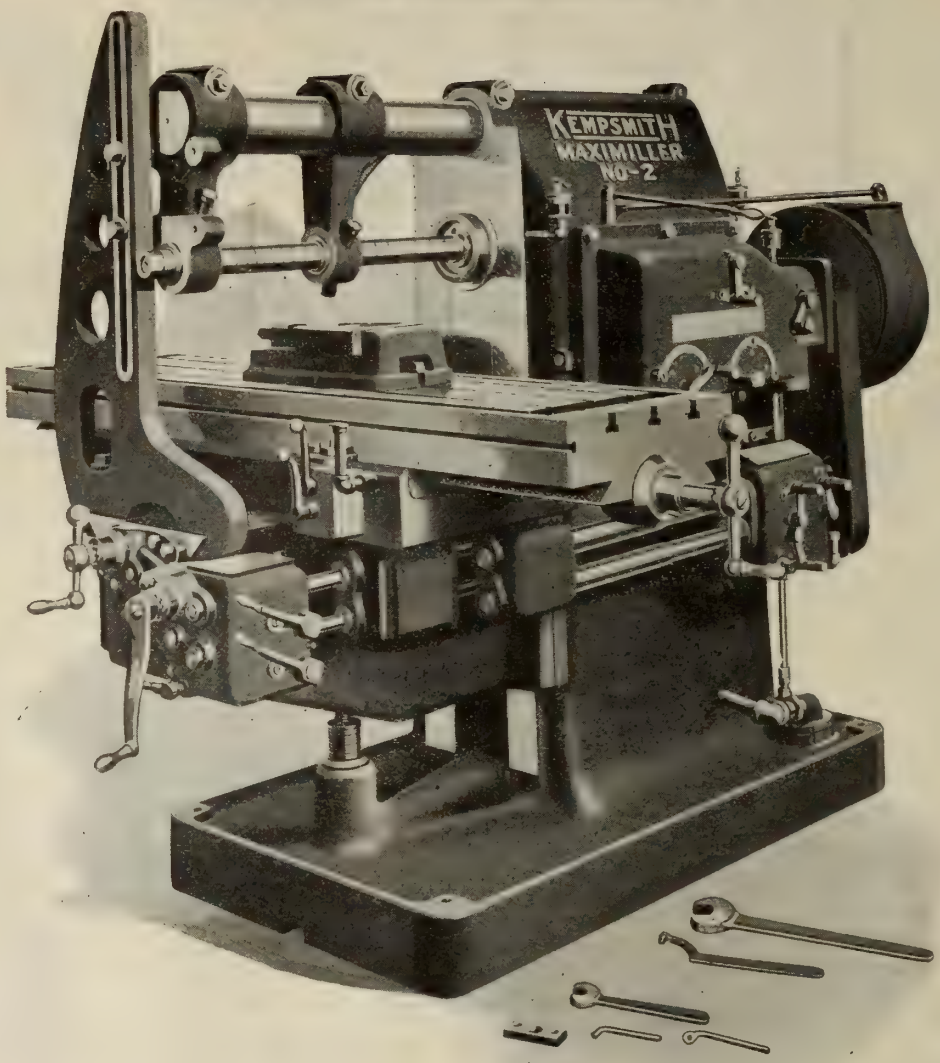
The Dominion Oxygen Company Limited announces the achievement of another milestone in its 1921 building program.

In July ground was broken in Montreal for a second large oxygen producing plant. Located at Magdalen, Lieber and Bourgeois Streets, this producing unit will have 10,000 square feet of floor space and will supplement the output of our Toronto plant by a 100 per cent. increase.

This expansion in manufacturing facilities will enable us to supply not only our regular patrons' steadily increasing demands for this highest purity product; but the needs of those who have wanted Dominion Oxygen and could not secure it.

And with the doubling of our producing machinery — employees and equipment—Dominion Oxygen consumers receive double insurance that our policy of filling all orders on the day of receipt will be rigidly maintained.

No matter where your location or what your requirements, an order dispatched to the nearest plant or distributing station — there are six of them—brings you the purest oxygen through the quickest service in the Dominion.



Dominion Oxygen Company, Limited

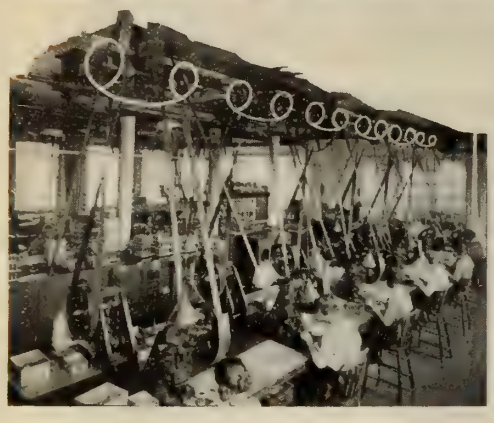
A New Machine For Repair Shops
THE LANDIS NO. 5 CYLINDER GRINDING MACHINES

LANDIS

The insistent demand for a machine to meet the requirements of automobile cylinders re-grinding, resulted in the designing and manufacturing of this new type grinding machine.

The machine will handle cylinders rapidly and accurately, and has a capacity great enough to include all makes and types of motor blocks, cast singly or **en bloc.** A centering device, the exclusive feature, properly locates the cylinder holes with center of wheel rotation. Vertical adjustment is eliminated which permits a quick set-up.



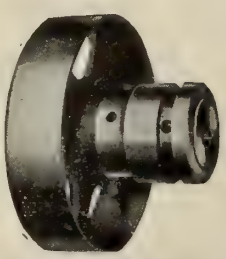
Together with other important features, this machine is ideal for your shop

Write for Circulars.

LANDIS TOOL CO. WAYNESBORO, PA.

NEW YORK OFFICE: 51 CHAMBERS ST.

THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

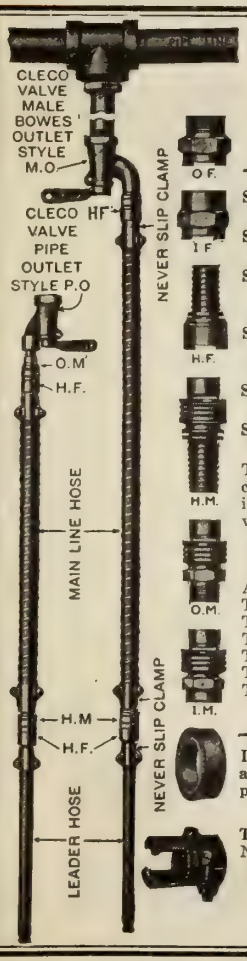
COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet



"Clutches As Applied to Machine Building." and our Yellow Catalog.

THE CARLYLE JOHNSON MACHINE CO. MANCHESTER CONN.

Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps and Cleco Grooved Hose Nipples and Hose Clamp Tool

STYLE O.F. is an Outside Thread Female Pipe End. made in sizes ⅜-inch to 1½-inch.

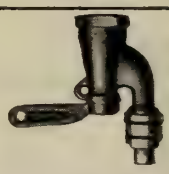
STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.



The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO VALVES

Style P.O. **Style M.O.** **Style A.**

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style M.O. Valve—Has 1 in. Inlet and Bowes Coupling Outlet, Connects with Bowes sizes ¼ in. to ¾ in.

CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lightening Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletins Nos. 43, 44, 46 and 47 mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

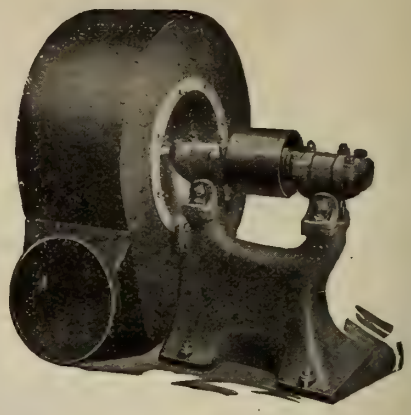
Saves $180 Weekly Since Cleaning Auto Parts With OAKITE

An Auto Factory now uses Oakite materials instead of caustic soda for cleaning fenders, dash plates and other sheet steel parts, because Oakite saves at least $180 every week in labor, and does faster and better work

Formerly had trouble with rejects after japanning ---which ran 6% to 8%, sometimes as high as 15%. Parts are now so thoroughly cleaned that japan takes perfectly and rejects are unknown.

With caustic it was necessary to wipe parts with gasoline before tack ragging. The elimination of this step, together with the fact that parts cleaned with Oakite are easier to wipe than parts cleaned with caustic, has made it possible for two men to do as much work as eight men did under previous conditions.

Write for booklet--- Oakite Service for Automobile and Aeroplane Manufacturers. Sent free on request to responsible concerns.



Resident Canadian Representatives: Mr. C. P. Murphy, Toronto, ar d Mr. C. Burgin, Montreal

Buying a Pig in a Poke

The buying of advertising space used to be buying "a pig in a poke." The quantity and quality of circulation was shrouded in mystery and often the bag was tied against investigation.

That day has passed. The advertiser no longer depends upon "mere claims." The Audit Bureau of Circulations has untied the strings to the sack and the circulation of the better class of publications is thrown open for the most searching scrutiny.

In buying advertising space in the Canadian Machinery you are not buying "a pig in a poke." Our A. B. C. statements will stand the analysis of the most exacting investigator.

Good Times Just Ahead

PROSPERITY is within our reach in Canada.
All we need to have and to hold it is a sane, sure grasp on its simple elements.

They are Industry, Integrity, and Faith.

These are the cardinal virtues of human relations. They are the underpinnings of healthy, natural business life and the foundation of a wholesome social system.

They are the fountainhead from which Progress springs. A well-known business economist has called them the "Fundamentals of Prosperity."

Your purchases are an expression of Faith. They are evidence of your Industry. Make them confidently from business institutions of Integrity.

Buying is the backbone of prosperity. An active market means more employment, steadier earnings; benefits are passed around.

Wise spending gives stability to earning and for that reason is far-sighted thrift and sound economy.

The call of to-day is for cheerful thinking, willing working and constructive action by you —everybody—NOW.

To-morrow's change for the better will come about through the combined efforts of each and every one of us.

By sheer force of numbers and co-operation, by the high power of heart and mind, we can put Business on a firm, stable basis.

We can do this because all of the material factors making for better business are right.

Let us link our faith with industry, our vision with courage, and forge ahead.

Let's make an uncommon effort toward a common end—Good Times.

BROWN & SHARPE AUTOMATIC GEAR CUTTING MACHINES

Accuracy

The accuracy of the finished gear is dependent upon the precision of the indexing mechanism. The indexing mechanism on

BROWN & SHARPE Automatic Gear Cutting Machines

meets every demand of accuracy as well as rapidity in operation. It starts and stops without shock and is locked positively for each tooth space. The large diameter of the index wheel which is keyed to the work spindle, further reduces the possibility of any inaccuracy in spacing.

Machining One Hundred Engine Pistons per Hour

Talk on Automatics—Examples of Work Produced These Including a Valve Stem Guide—Engine Valve Cage—Steering Gear Side Plate—Automobile Fan Hub—Air Drill Cock Body.

By J. H. MOORE

LIKE practically everything else, machine design has developed and improved with the times. This is especially true in the automatic field, until at present, even a machine designer catches himself shaking his head when looking at an automatic and remarking "It's almost human in its action. Isn't it?"

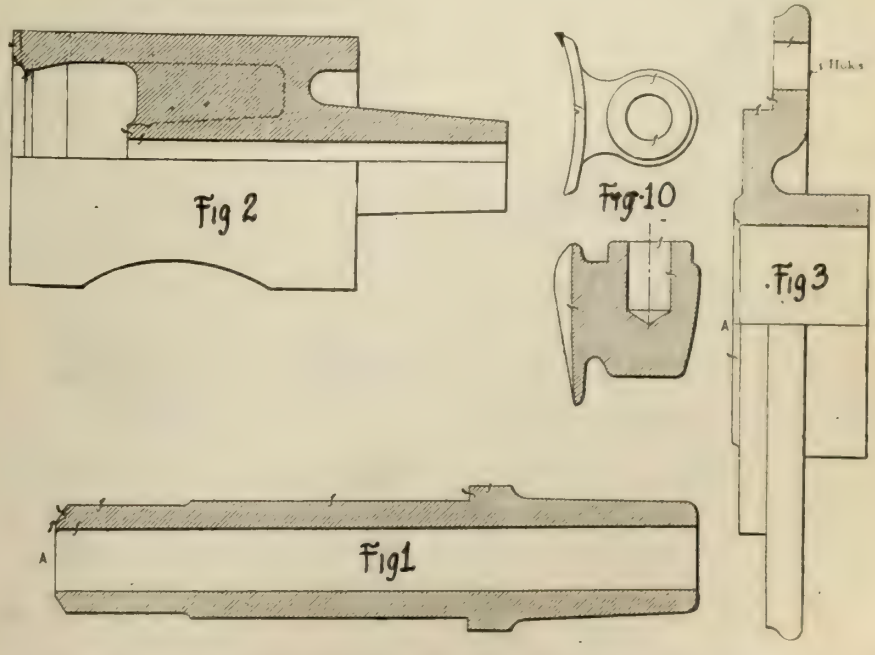
Wasted movement has been attacked from all sides, the chief aim being to produce parts accurately and in the shortest possible time.

The automatic, whose work we are going to consider in the present article is built in two distinct types, —single and double head. The former type is used for machining pieces which require operations on one end only, or on parts which already have one end machined; while the double-head style handles parts requiring operations on both ends. The cost of handling both ends at once is self-evident, viz., that it only takes one half the time that would be required were each end finished separately in a single head machine.

These machines have several spindles ranging from four to six. These spindles revolve and carry the tools where several pieces of work are held stationary in a multiple chuck turret, which, when it indexes, brings each piece of work in line with the next succeeding tool. All machining operations take place in the intervals marked by the automatic progression of the turret indexing mechanism, the time necessary to complete a piece involving a series of operations within the time required for the longest single operation only—or sub-division thereof.

In the case of the single head type the turret advances and feeds the work against the revolving tools, while in the double-head style the revolving tools advance from both sides, thus performing their operations on each end of the work. In this way a series of operations is carried out on several pieces simultaneously, the parts approaching completion as they progress from one tool to another.

The tool spindle centres are in line with the centres of work holding chucks while the omission of a spindle opposite the upper turret position provides an idle chuck, which allows the operator to remove the finished piece and insert a rough part while the machining operations are progressing at the other positions.



It would be well to add that various styles of work holders are used, these including two and three jawed chucks; draw in arbors; integral chucks; in fact, any other special work holder that may be necessary to hold the pieces securely.

This, briefly, explains the procedure. Certain sizes of machines are better adapted for some classes of work than others, but this is only natural and the examples of work which follow will give readers a good idea of the types used.

Examples of Work

Fig. 1 shows a valve stem guide made of grey iron, which is finished at one setting on a machine having a maximum swing of five-and-a-half inch diameter outside of chuck jaws.

The operations are to turn, drill, face and ream in the time required to drill one third the length. Subdividing the drilling operation not only greatly increases production, but insures a true hole. The performance of the operation in three

FIGS. — 1, 2, 3, AND 10. TEXT MATTER EXPLAINS OPERATIONS PERFORMED.

Illustrations of work and machines, through courtesy of the New Britain Machine Co., New Britain, Conn.

stages also removes the tendency for the drill to clog up and run out. Stellite turning tools are used for turning and facing, high speed drills being the medium adopted for the centre hole. Production on this piece is 100 per hour.

The next example, Fig. 2, shows a grey iron gasoline engine valve cage. This piece is completed at one setting in a machine having a maximum capacity of seven-and-a-half inches outside of jaws, and the operations are to face end, rough seat, drill and ream. On this work intenal high speed spindles are used, the main spindles handling the large diameters, while the internal spindles take care of the drilling operation. The high speed spindles turn at approximately five times the speed and one fifth the advance of the turning tools, thus increasing production, and at the same time reducing drill upkeep. Sixty cages are produced every hour by this method.

At Fig. 3 is shown a steering gear side plate which is produced at the rate of 120 per hour. In this case the piece is made of malleable iron, and is finished at one setting on a single head machine of the same size that completed Fig 2. The operations are, bore, turn, face, chamfer, ream, and drill four holes in the flange with a multiple drill head.

On work of this nature, where the flange has to be machined as well as drilled with accurately spaced holes, a multiple spindle drill head can be placed on the machine. These drills operate through guide bushings located from the reamed hole, thus insuring uniform accuracy without involving an additional operation.

Fig. 4 shows a carburetor mixing chamber cap that is finished at one setting on a single-head machine having a maximum capacity of five-and-a-half in. diameter outside of jaws. The operations are, turn, face, drill centre, and flange holes. By means of high speed drills installed within the main spindles, it is possible to drill the centre and turn the flange simultaneously, yet at the same time maintain the proper cutting speeds at the tools. There are three holes in the flange, these being drilled with a multiple drill head without an additional operation. One-hundred-and-thirty of these parts are produced per hour.

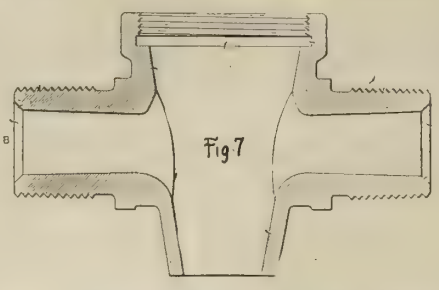


FIG. 7—AN AIR DRILL COCK BODY WHICH WAS SUCCESSFULLY PRODUCED.

Automobile Fan Hub

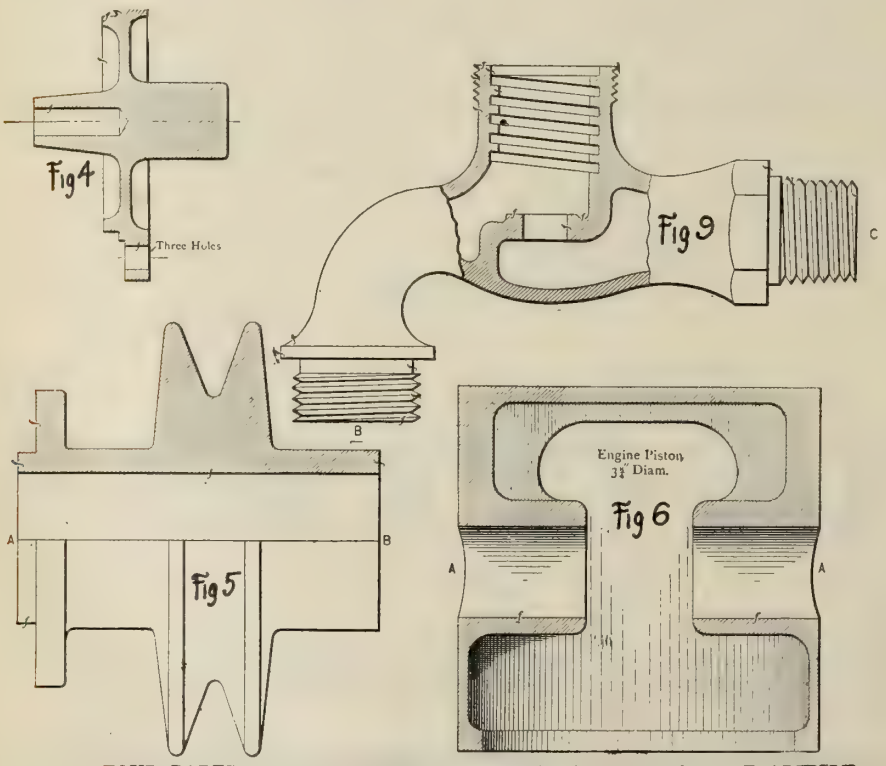
At Fig. 5 is shown a good example of double head machine work. The part is an automobile fan hub made of grey iron. The piece is finished at one setting on a machine having a maximum swing of 7¼ in. outside of jaws, and following are operations: The flange and hub of end A are faced; end B is faced and bored; while end A is bored and reamed. The production on this part is 50 per hour.

Another double-head machine job is shown at Fig. 6. The gasoline engine piston is finished at one setting and the operations are: drilling both sides, boring and reaming. This is a good example of double head work, and in this case the bottom is faced and the inside bored before coming to the machine. he turret is equipped with special fixt es which locate the pieces from these chined surfaces. The pistons are dr ed and bored from both sides simultane sly, while the reaming is completed through from one side only, thus in ing absolute alignment of the two ings. The tools operate through guide bushings, and the productio these pistons is 100 per hour.

Fig. 7 is an ideal illustration, in that it defines clearly the use of s and double head machines. In fa shows where both types can be us advantage. The part is an air drill body made from malleable iron, an end A is finished on a single head chine, while the ends B and C are pleted on a double head type.

The operations on end A are: bore, taper ream, neck, and tap; at B and C the steps are to turn, chamfer and thread. The productio end A is 90 per hour, while the two B and C are completed at a like In this way the single head ma handles all work at end A in the required to rough taper ream, whil double head machine completely fi both ends simultaneously in the required to rough turn one end onl

Fig. 8 is a typical illustratio work admitting the use of a double combination tap and die head. On a head both the tap and die are from the same spindle, the tap le with its coarse pitch, and the di lowing at a rate corresponding wi finer pitch.

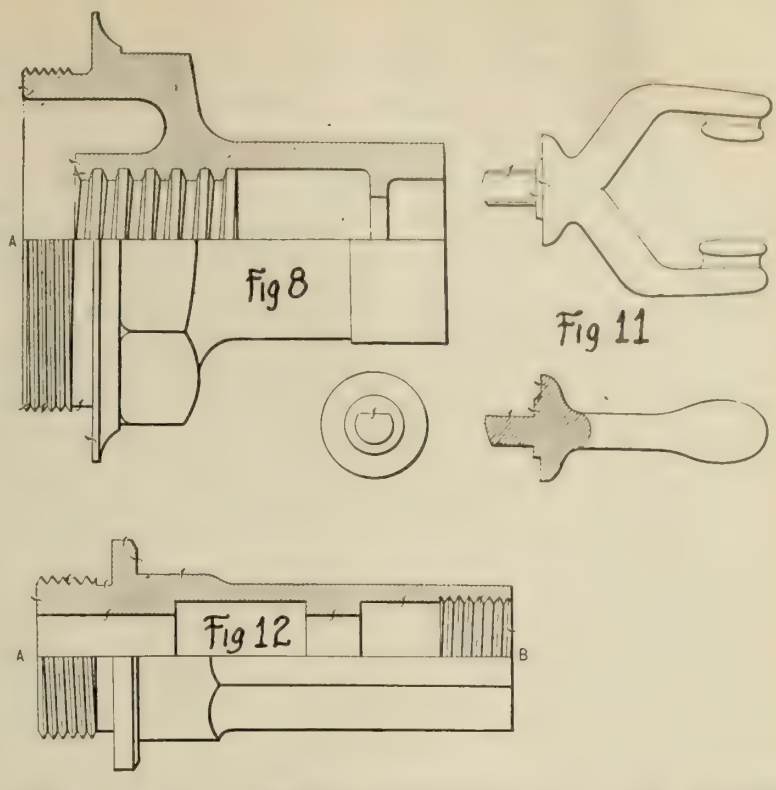


The part is a bronze valve b and it is finished at one setting single head machine of 7½ in. ca outside of jaws. The piece is turned, faced, necked, tapped and t ed at the rate of 160 per hour, a entire part is finished in the t the boring operation.

Bronze Bibb Body

A compression hose bibb body, of bronze, and finished at three se on a single head machine of 5 maximum diameter outside of ja shown at Fig. 9. The operation End A, bore, turn, face, seat, nec of thread, tap and thread. End B turn, back, neck, back of threa flange, and thread. The other f has to be bored, turned, face threaded. On face A the produc 280 per hour; on face B 300 per and on face C 320 per hour. The ination tap and die head already red to works in to good advanta side A of this piece.

Fig 10 shows an oil stove elbow of brass that is finished at one s on a single head machine, the tions being to turn, face, drill, an 600 are produced per hour. At is shown a stove doorhandle o iron which is finished at one on a single head machine, the tions being to turn end, face an shoulder, face flange, and mill f shank, The production in this 500 per hour.



It will be noted that in both thes

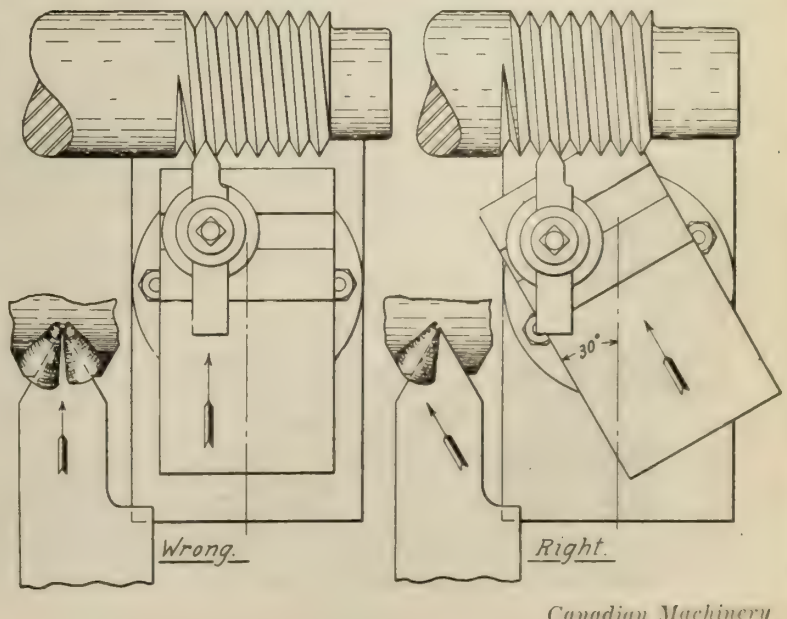
FOUR PARTS, THE DESCRIPTION OF WHICH IS GIVEN IN THE ARTICLE

a illing operation is included as well as the regular turning, drilling, and boring operations. In such a case, a special off-center milling attachment is used, so that milling can be accomplished incidentally with the other operations. Uniformity in distance between centers of the two operations is assured by reason of their being performed simultaneously and at the same setting.

The concluding example, Fig. 12, shows a door check gland made from malleable iron. This part is finished at two settings in a single head machine, and the operations on face A are:—Turn, bore, face, ream, neck and thread. On face B, the part is turned, bored, faced and tapped. The production at end A, is per hour; at end B, 95 per hour. On this work it was absolutely essential that the machining operations should be concentric and parallel with the octagon exterior. For this reason draw-in octagon collets were used in the universal work holding turret, this insuring the desired

FIGS. — 8, 11 AND 12. SHOWING THREE EXAMPLES OF WORK COMPLETED.

PORTABLE PETROL DRIVEN CRANE.



Steam and electricity have hitherto been the chief means of driving cranes of large size larger than could be operated by hand, but the compactness and the convenience of the petrol engine have recently to its application to cranes of lighter grades. A good example of this new type is a portable crane designed by a British firm mainly for use in building operations. It is driven by a four-cylinder petrol engine and is made in two sizes, one capable of lifting half a ton and the other with a capacity of one ton. An important feature of this crane is the special gear which enables the driver, simply by moving a control handle to lift a load at any speed from a crawl to the maximum, while the engine runs continuously at its most efficient speed. If for any reason the handle is released the brake is automatically applied on the instant and the crane comes to rest with the load suspended. The engine acts as a counterweight and the whole equipment is so light and well-balanced that it can be easily moved about on its four wheels or slewed as desired.

WATCH THIS.

If for any reason it is necessary to blow out an acetylene pipe line with compressed air, great care must be taken to eliminate all air and gas mixture from every branch of the line before starting to use welding and cutting torches. Air and acetylene mixture in the pipe line is exceedingly dangerous; a flashback from a torch may cause rupture of the pipe line.

Thread Cutting on the Lathe

When cutting V-threads on the engine lathe it is nearly always advisable to swing the compound rest to an angle of 30 degrees with the main cross slide. The point of a cutting tool loses its keenness due to the heat generated through friction, not alone of that between the tool and the work, but also by the curling of the chip and the breaking up of the same. When the feed of the tool is at right angles to the axis of the shaft, the cutting takes place on both sides of the tool—as shown at the left of the sketch—causing chips to curl against each other and creating excessive heat, and breaking down the point rapidly. At 30 degrees inclination the cut is made as shown at the right, allowing chip to curl freely and retaining edge longer. Feeding is done with the compound rest. When thread is just about finished, feed lightly, and alternately, by the cross and the compound feeds.

Canadian Machinery

Grinding Practice—Variety Of Fixtures Used

Grinding Machines are Very Diversified in Character—Grinding Conditions Should be Closely Considered by Operators—Examples of Cutter Grinding and Other Fixtures

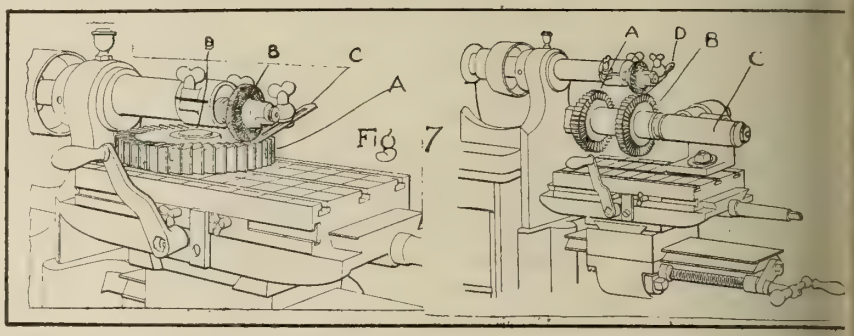
By F. SCRIBER

IN no field of the machine tool industry can there be found the basic differences in design as in that of grinding machines. When we say lathe, shaper or milling machine, at once there leaps to the mind a conception of the general types of machines employed for this purpose. When we say grinding machine we have in reality left no impression on the mind, for in this class of machine tool there has been incorporated features which are to be found in most every type of tool. For example, there are plain cylindrical grinders, surface grinders, internal grinders, tool grinders, cam shaft grinders, oscillating head grinders, vertical surface grinders, and a multiplicity of varying shapes and construction incidental to these general principles. Nevertheless, it is surprising, in spite of this fact, how one general type of machine will be used in many factories for various styles of work, including tools, much of which might be more suitably handled on a machine of specialized construction. The purpose of this article is to dwell briefly on the principles of some of these machines, to show how the grinding wheel comes into contact with the work, and describe a few grinding set-ups.

Referring to Fig. 1, we have shown illustrations of two machines, the lower view depicting a small internal grinder of a type known as a bench grinder. On this machine the wheel shaft A is driven by the shaft B, these being contained in a suitable adjustable bracket mounted on a base C. The work is held at D, on spindle E, said spindle being made to revolve the work. The work spindle is carried in a bracket F, which has longitudinal and cross adjustment, all of which is mounted on a pivoting piece G contained in the base of the machine. This construction permits of adjusting the work around to various angles so that either tapers or straight holes may be ground, and also permits of radial grinding. The machine is usually set on a bench or stand, and when grinding radial surfaces the work is set the required distance from the center from which the work carrying spindle oscillates. Graduations on the surface X of this pivotable bracket permit of accurately setting the work to the required angle.

Now let us consider the machine illustrated at the top of Fig. 1. This is of the type usually employed for medium and heavy cylindrical grinding in which work H is ground by a wheel J, the work b revolved and traversed longitudir past the wheel by means of table K, action of which is controlled by the dles shown at the front of the machir

Figure 2 depicts a few typical grin jobs. The first of these is a tapered ib ground as indicated at G. This surface grinding job and requires a ture for holding it on the proper ar Below at Y is shown a tapered spi



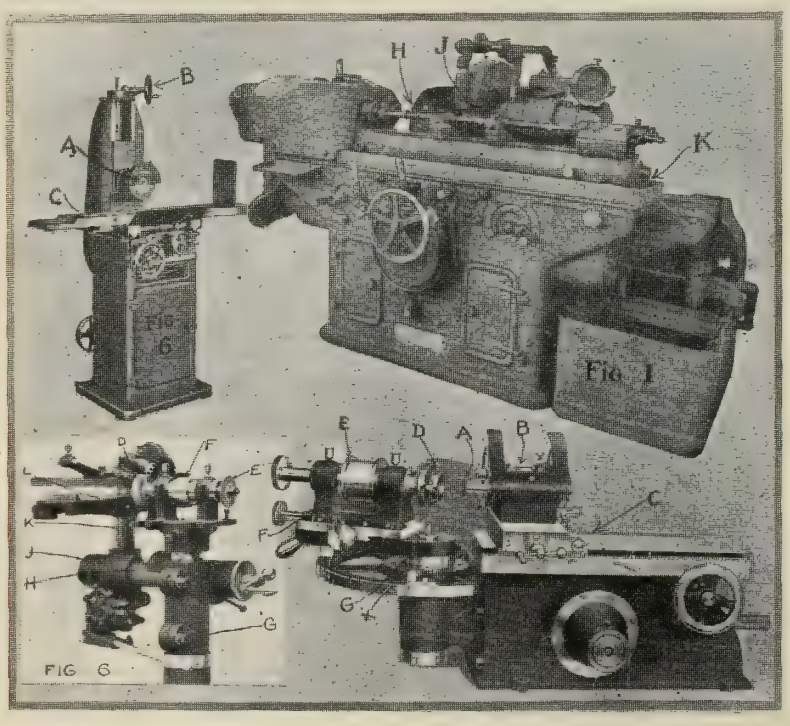


FIG. 7. — TWO SET UPS FOR CUTTER GRINDING.

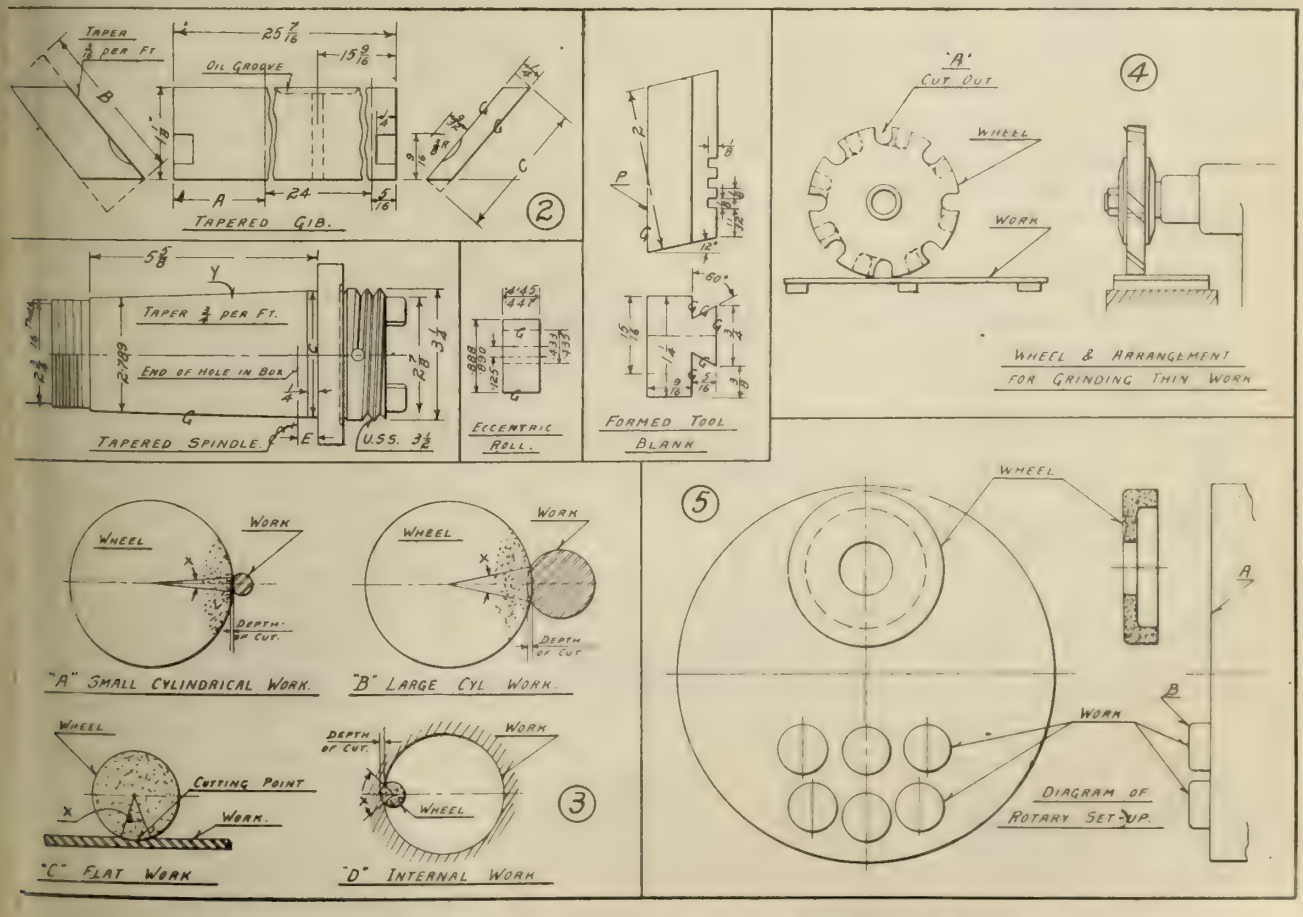
This is a cylindrical grinding job, piece being ground as indicated at G It is necessary to set the grinding mac table on an angle to grind this taper. W is shown a form tool blank. Th a surface grinding job, it being cus ary to cut a form in surface P, of shape to make the work wanted screw machine, and after hardening tools, to grind the surfaces indic using formed grinding wheels w necessary. At Z is shown an eccer roll on which it is necessary to grind hole and outside diameter. The could be ground on a machine such shown in the lower view of Fig. 1, v the outside eccentric diameter menti could be ground on a machine of type shown in upper view by settin on an off-set arbor.

Before going further it is desire point out certain grinding condit which should be closely considered operators and those who have charg such machines. These relate to w contact and the handling of the wh on the machine, Fig. 3, which is a grammatic illustration emphasizing s of these features.

At A is shown a grinding whee contact with a piece of work of s diameter X. This view and arc indic the length of grinding wheel contact the work. At B is shown a wheel in tact with a piece of work of much la diameter, and the point that I wis bring out is this, that owing to the l arc of wheel contact for taking the s depth of cut on the large diameter, tive to the same depth of cut on the s diameter, it is desirable that the speed of the machine be slower

FIGS. 1 AND 6. — SHOWING VARIOUS STYLE GRINDING MACHINES.



guding the large diameter, than when guding the small diameter. This condi on prevents excessive wheel strain ar overheating of the work. At C is shvn a grinding wheel in contact with a fla piece of work for surface grinding, an here it will be obvious that the arc of ontact is even larger for a given de h of cut. At D is shown a small rding wheel in contact grinding a o in a piece of work, and it will be noicl that the arc of contact is relatively ne long. The importance of regulatng he peripheral speed of the work to a e fine degree will be readily appreisd by considering the conditions exstg when grinding work such as hen in these diagrams. It is an imoant part of the operator to so regut the work speed of his machine that fi a given grade of wheel, a definite eh of cut, and a grinding wheel reding at a proper cutting speed, that t mount of stock removed will be the u during each feed of the work past tewheel regardless of whether cylinrid, surface, or internal grinding is i done. As is well known, a grinding l of a given grade will vary some h in cutting properties, so it is pracy impossible to set definite rules for l but an experienced operator should oo become familiar with and underg these basic conditions, and govern i peration of the machine accordingly, l is to obtain maximum production nstent with a good grade of work.

I Fig. 4 is illustrated a wheel which has been cut away as shown at A. This wheel was used for surface grinding on work which became warped on account of extensive heat generated in grinding, and in cutting the wheel out as shown, in addition to obtaining intermittent contact with the work, the revolving wheel creates air chambers and acts as a fan which helps considerably in grinding thin flat work. It will be noticed in this connection that the slot is cut diagonally across the face of the grinding wheel, the object being to have part of the wheel cutting at all times so that the wheel and grinding wheel spindle will not vibrate as the slots pass over the work. As the wheel revolves, the work traverses under the wheel lengthwise, and at each passing of the wheel across the work, the table carrying the work is fed crossways, so as to present an unground surface to the grinding wheel every time the work passes under the wheel.

Another principle often employed in grinding is to grind with a vertical wheel and a rotary work carrying table. A setup of this type is shown in Fig. 5, where the work is mounted on a table A, which may or may not have a magnetic chuck on it. The wheel revolves at high speed and is brought down in contact with the upper surface B, and as the table revolves under the wheel all the parts held on the table are brought intermittently in contact with the wheel and are thus ground. When grinding on this type of machine the work has quite a long contact with the grinding wheel, therefore the speed of the work in its rotation must be regulated accordingly.

Fig. 6 depicts two types of grinders which are very popular in the tool-room. The one at the top is a surface grinder in which the grinding wheel spindle A is carried in a slide and is fed vertically down upon the work by means of a hand-wheel B. The table C travels longitudinally under the wheel and carries the work, while this same table is carried in a saddle and is fed crossways under the wheel by means of a hand-wheel at the front of the machine. At the bottom at Fig. 6 is shown a tool grinder. This is applicable for use when grinding various types of cutters and reamers, the work carrying members being made universal so that with suitable attachments most any type of cutter can be ground. Two grinding wheels D and E are carried on a spindle driven by pulley F. These are mounted on a column to which is attached a bracket G which is free to swivel thereon. Attached to this swivel bracket is a post H, upon which is mounted a swivel unit J. In this unit is a post K carrying a platform L on its upper end to which is attached various fixtures for grinding different types of tools.

Two examples of cutter grinding are shown at Fig. 7, the one view showing the side teeth on a side milling cutter being ground, the cutter being indicated at A, the wheel at B, while C is a suitable gauge. The cutter is placed over a stud D, and one tooth on the cutter comes against the gauge C, thereby locating it

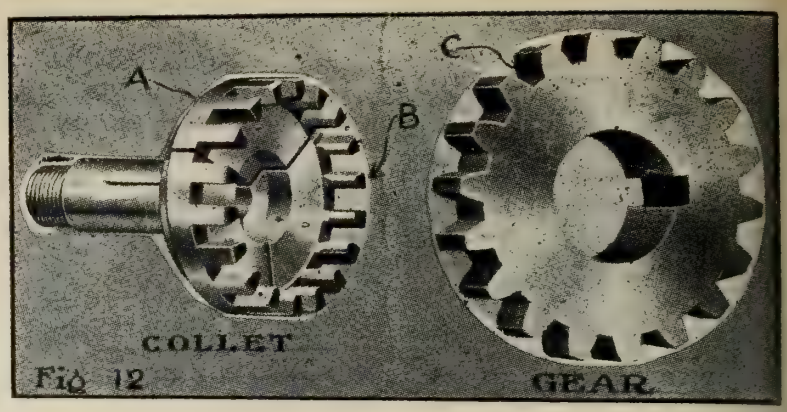
FIGS. 2, 3, 4 AND 5. — SHOWING VARIOUS CONDITIONS MET WITH IN GRINDING PRACTICE.

radially about the stud D. The cutter, which is on a table, is then fed crossways under the grinding wheel, thus grinding one tooth. It is then revolved to the next tooth and this is likewise ground, continuing until all the teeth have been finished. The other view shows the same machine arranged for grinding the face of two of these milling cutters, and it will be noticed that the cutters A and B are mounted on an arbor in a bracket C. The gauge D comes against one tooth and locates the cutter radially on the arbor, when by feeding the table crossways the face of one cutter is ground, or if both cutters are to be the same size, the wheel is fed across both cutters. If they are not to be the same size, one cutter is completely ground on its face, following which the knee of machine carrying the cutters is fed up the required distance so that the next cutter can be ground to the correct diameter.

Having treated at some length on the generalities of grinding machines, and illustrated some principles of construction and operation, the remaining illustrations will show various methods of holding work while grinding. The first of these is the internal grinding job shown at Fig. 8. This is a rocker arm made in two sections bolted together. The arm is carried on a cast iron face plate A held to a revolving spindle on a cylindrical grinding machine. Two studs B and C are mounted on this face plate so that the two small holes on the rocker arm will slip over these and locate. The nuts D, when tightened, hold the rocker arm in place, and a small grinding wheel E, revolving at high speed, is fed longitudinally forward and back through the large center hole of the rocker arm, this of course doing the desired operation. The cross feed of course is used to feed the grinding wheel into the work to the required depth of cut, thus bringing the work to desired size.

Grinding in the tool-room at the present time is practically indispensable where any quantity of accurate work is to be produced. A large percentage of tool-room grinding consists of gauge grinding, cutter grinding, and tool grinding, much of which is handled on a surface grinder similar to the type shown in Fig. 6. A good percentage of the work ground in the tool-room is left to the tool-maker's judgment as to how it should be set up and handled. In Fig. 9 is shown a single point threading tool A being ground, and as quite a number of these tools had to be made from time to time, it was found advisable to use the fixture shown for holding them at the correct angle while grinding the surfaces B and C. As is obvious from this illustration the cutter to be ground is held in the formed block D which holds it at an angle so that the grinding wheel E may be fed across the face of the tool. The clamp F, tightened by nut G, holds the tool securely in the block, and after one side has been ground, it is laid aside until all other tools in the batch are similarly ground, following which they are reversed and the opposite side C completed.

An example of gauge grinding is shown in Fig. 10, this being a tool-making proposition. The gauge A is held in a vise B and is not removed therefrom until the completion of the grinding of surfaces C and D. The grinding wheel E is fed across the surface D in the usual manner until this surface has been rough ground, after which the wheel is raised and surface C rough ground, the upper surface of the wheel coming in contact with this latter mentioned face. The finish grinding of surface C is then completed. The wheel E is next lowered and surface D finish ground, the work testing between the surfaces by means of his measuring instruments until they are the correct size.



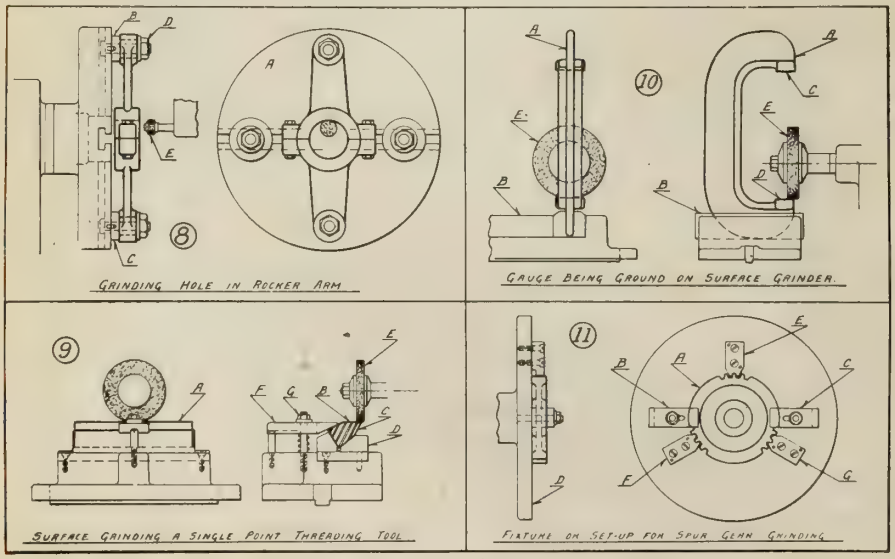


Fig. 12

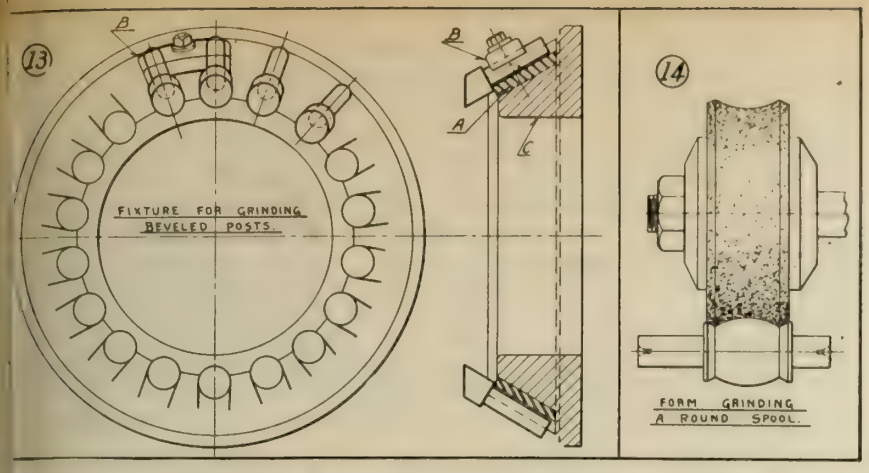
COLLET USED FOR HOLDING THE GEAR SHOWN.



A fixture suitable for holding a gear while the hole is being ground in a cylindrical grinder is shown at Fig. 1. The gear A is held to a face plate on the revolving head of the grinding machine by means of two clamps B and C, which hold the gear against surface D in the usual manner. To locate these gears centrally on the face plate, three pins E, F and G are attached to the plate, these having one tooth space accurately cut in them so that they will just mesh the gear on the pitch line, thereby locating the gear centrally from the pitch diameter. After grinding the hole, the gear is placed on an arbor and the side diameter ground. This insures that the hole of the gear will be accurate with the pitch diameter, and likewise that the outside diameter of the gear will be concentric with the hole and pitch diameter.

Another method of holding a gear while grinding is shown in Fig. 12. This consists of a spring collet A, having a series of teeth cut into a surface B. The gear C is placed into this collet, and the collet is caused to contract and grip the gear on the pitch diameter in the usual manner, the collet having three slots cut in it for this purpose.

Mention was made in Fig. 5 of a rotary surface grinder, and an example of work being held on one of these grinders is shown in Fig. 13. Here we see a number of beveled posts held in a fixture which is attached to the rotary table of the machine. The posts are held on an arbor, all being located in a ring A, being held thereto by clamps B. These clamps grip two posts each, holding them securely to the ring. The ring is held to the face of the fixture C by means of screws and dowels, and with a number of parts set in the manner shown the vertical grinding wheel may be brought into contact with the posts, all the bevelled surfaces being thus ground simultaneously. Many parts machined on a rotary surface grinder are merely held thereto by means of a magnetic chuck where the work may be laid on a flat surface.

FIGS. 8, 9, 10 AND 11.—SHOWING VARIOUS GRINDING OPERATIONS.

IG 13 AND 14. — FIXTURE FOR BEVELED POSTS, ALSO METHOD OF FORM GRINDING A ROUND SPOOL.

Before concluding, it is desirable to al attention briefly to form grinding. g. 14 is shown a formed spool which round by feeding the wheel trans- ly into it, the spool of course re- ing while this is being done. Many ferent shapes are ground by this od, it being of course necessary to the wheel to the proper form for ing the work.

While extensive description of any one type of machine has been avoided in this article it is thought that the versatility of the application of grinding wheels will be more generally appreciated from its perusal. A very small portion of the grinding field has been covered and anyone confronted with grinding production problems will do well to investigate the widely divergent designs before selecting the type most suitable for his particular need, or concluding that the job is not applicable to grinding.

RECORDING THE TEMPERATURE CURVE IN NEW CONTINUOUS KILN FOR THE CERAMIC INDUSTRY.

By H. CHAMBERS.

The General Combustion Company has recently installed a continuous kiln for the heat treatment of ceramic ware at the plant of Lennox Inc., Trenton, N. J. Figure 1. shows a cross section of the kiln. It will be noted that the material to be treated moves through the kiln on cars. The car on the right hand side moves in the opposite direction to that on the left. The reason for this movement of the cars in opposite directions will be apparent on inspection of Figure 2, showing sectional plan and elevation of the kiln.

The material to be treated enters the kiln cold and is gradually heated to a maximum temperature at the center of the kiln, which portion is known as the "heating zone." After passing through this heating zone the material gradually becomes cooled as the car approaches the exit end of the furnace. The reason for using two chambers in which cars move in opposite directions through the kiln is to increase the thermal efficiency by making possible a heat exchange between cars opposite one another at any point in the kiln. Due to the fact that the material on one car is increasing in temperature while the material on the car opposite to it is cooling, air currents are set up by which heat is transferred from the cooling car to the one opposite which is increasing in temperature.

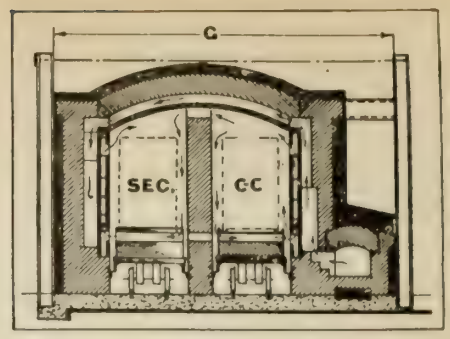


FIG. 1. — CROSS SECTION THROUGH FIRING ZONE.

In the heat treatment of one class

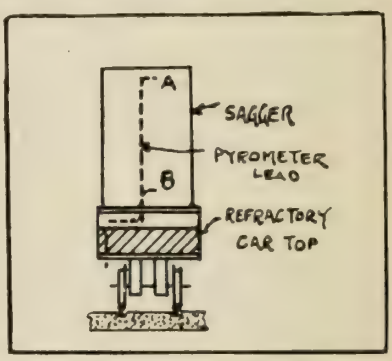

FIG.3. — SHOWING CAR TOP, SAGGER AND PYROMETER LEAD.

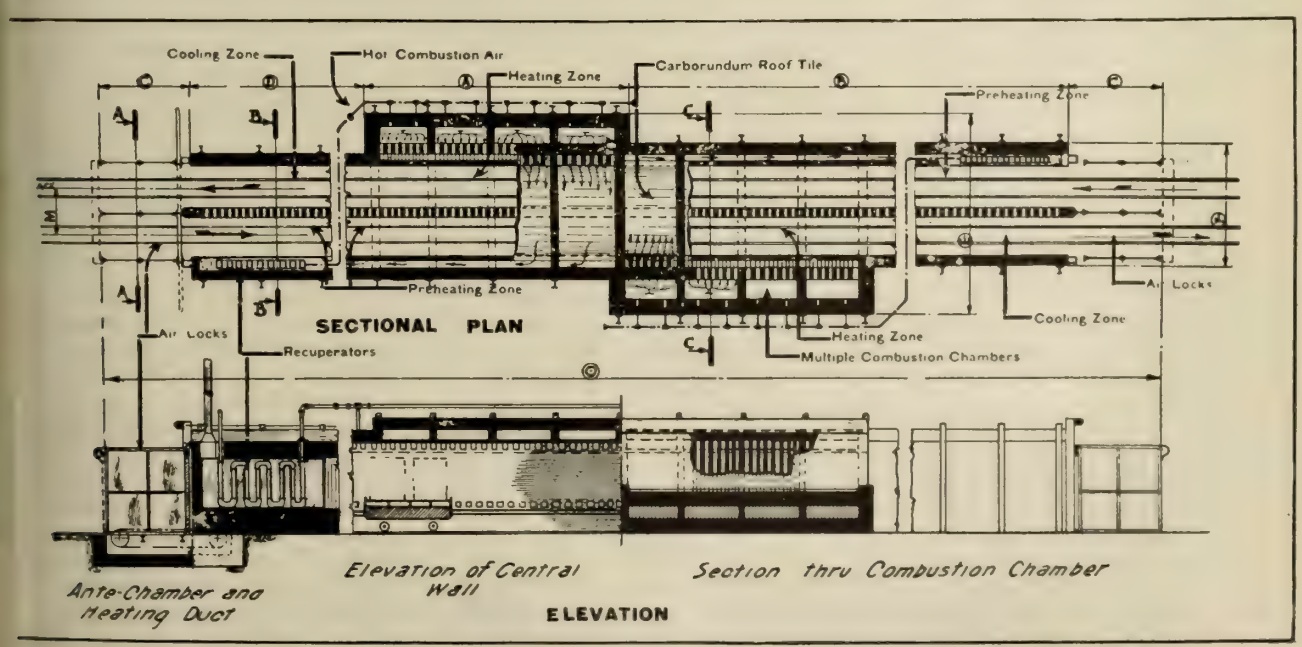

FIG. — SECTIONAL PLAN & ELEVATION OF A DOUBLE CHAMBERED CAR TYPE TUNNEL KILN FOR HEAT TREATMENT OF CERAMIC WARE. NOTE THE FIRING ZONES OF THE TWO CHAMBERS ARE LOCATED DIAGONALLY OPPOSITE EACH OTHER.

of ceramic ware, it is desired to gradually heat the ware for a period of about thirty hours, to a temperature of 2,000° F. The ware is held at 2,000° F. for a period of about 3 hours and then gradually cooled over a period of about sixteen hours. The ware is packed in cylindrical clay saggers standing about four feet high on the car. The temperature of the ware inside the saggers must follow a pre-determined time —temperature curve, within fairly close limits. Curves taken have shown excellent results.

Figure 3 shows the manner in which the two thermo couples, A and B, are placed in the saggers. A and B record the temperatures near the top and bottom of the saggers respectively. The cable connecting the couples with the Recording Pyrometer is sufficiently long to allow the car to travel the full furnace length of sixty feet. The connecting cable is either fed by hand or unrolled from a drum as the car progresses through the furnace. Successive cars having refractory tops serve as a moving hearth for the heating chamb Hydraulic rams travelling one foot p hour move the cars through the kiln.

For correct furnace operation the t variables which must be determined a firstly, rate of travel of cars throu kiln; secondly, temperature of heati zone. Having fixed the rate of trav of the cars, the correct temperature the heating zone is obtained by repe ed trials until the correct time-temper ture curve is obtained.

Hints on Packing and Shipping Goods for Expor

Packing Should Be As Light As Possible, Keeping In Mind The Strength And Resistance to Shocks Necessary to Carry Goods In Proper Condition to Their Destination. Present Method Shows Room For Improvement

PACKING and Shipping for export will always be a live subject. Many hints have been given, Major Gordon B. Johnson, Trade Commissioner in Glasgow, Scotland, being the latest to air his views. Here is what he says:—

"No part of the technique or machinery of overseas trade is of more importance than the packing and despatch of shipments. On the manner in which goods are packed depends their condition on arrival at destination, the amount of rail and ocean freight charged, and the amount of customs duties imposed at the port of the country of destination. Packing should be as light as possible keeping in view the strength and resistance to shocks necessary to carry intact and in proper condition to the end of the journey, not forgetting the numerous and exceedingly rough handlings to which all overseas shipments are subjected, and certainly not forgetting the possibilities of pilferage. This evil has grown enormously since a few years ago and is so great that marine insurance companies will no longer accept risks, unless the packing is especially well done. For example, tin-lined cases. If it is necessary to increase the weight by means of a heavier caes with metal bands and straps in order to obtain sufficient strength, then this course should be followed. It should be borne in mind that ocean freights are charged according to weight or measurement at the option of the transporting company, so that all shipments regarding which there is a possibility of a measurement basis should occupy as little space as possible.

In the case of shipments to Great Britain where import duties apply to only a small number of articles, the wishes of the buyer should be carefully considered, as they are based on a long and thorough knowledge of overseas trade and its requirements. and on the customs and preferences of the market concerned.

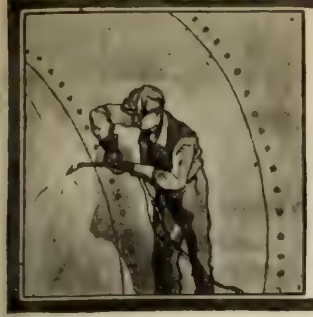
Canadian methods of packing following American methods, are looked upon by importers overseas in a general way as inferior to British and Continental methods, particularly British, and this is the impression that anyone is likely to have who has knowledge of Canadian overseas trade in general. Nevertheless it is surprising, on investigation, to land so many Canadian products of diverse kinds packed and shipped not only in an exemplary manner, but in some cases in a way not reached by shippers of any other country. On the whole, however, there is decided room for improvement.

Marking.

Packages for export should be marked with the mark of the consignee, the point of destination, the serial number of the package of the shipment, the weight and dimensions. Such marks should be plainly stencilled. Labels and tags, whether tied on or glued should not be used except where absolutely necessary, and only in cases in which stenciling is inapplicable. The mark of the consignee is usually placed inside a geometrical figure corresponding to his mark in the bill of lading, the serial number of the package and the point of destination being placed outside.

Handling at the port of destination, particularly in customs houses, is facilitated if the marks are in duplicate, on opposite sides in the case of packing cases.

Lumber.



As a rule Canadian lumber appears to be shipped in a way that calls for little or no criticism, but there are one or two points in the minds of importers in the Scottish market regarding shipments which should be brought to the notice of such of the shippers as ha failed in the past to observe certa precautions. For example, large floori should be shipped in fairly small bu dles, wired and protected at the edg Anything thicker than 1-inch st should be shipped loose. Thin lumb should be properly bunched—that the widths should be picked, and ca observed that the narrower widths not placed inside the wider, as the la ter, because of the tight wiring of t bundle and because they overlap t narrow widths, are subject to being be lengthwise and thereby broken. In fa this often happens.

Each piece should be properly mar ed with the consignee's mark shown the bill of lading. Deals are marked the same way sometimes stencilled the ends.

What appears to be legitimate grou for complaint among importers of lu ber is connected with bills of lading, a is directed against shipping compani rather than against the exporters. bill of lading issued by the shipowne to the shipper may state that so ma bundles of lumber have been receiv on board, containing in total so ma pieces. As bundles may be, and pr bably are, of different sizes, the co signee has no redress against the tran porting company if pieces are missi by bundles becoming loose through wi or string giving way. Similarly t statement in the bill of lading regardi a shipment of loose lumber that " many pieces more or less on board to delivered" is also unsatisfactory to t consignee. A definite number of piec should be stated, thereby providing "clean" bill of lading.

Another cause of complaint is in co nection with the through bill of ladi for rail and ocean transport. Buyers this side would feel more secure

WELDING AND CUTTING

Fillet and Butt Welding by the Electric Arc

Fillet Welding is Very Useful in Sealing Leaks in Riveted Joints —Various Methods of Producing the Weld—Butt Welding— How to Successfully Perform Such Welds.

IN THE July 14th issue of "Canadian Machinery" we discussed the welding of heavy sections by means of the electric arc. In the present article we shall consider fillet welding and butt welding as accomplished by the same process. Fillet welding is very useful in sealing leaks in joints made with rivets, or by any other method, but care must be taken in case the joint is loose to make it secure and rigid before trying to seal with the fillet weld, because with the loose joint the entire strain is thrown on the fillet which, in general, is not of a cross section equal to the original plate, and hence weld will be blamed for tightness failure where an entirely different cause was the trouble. If the joint cannot be made tight before welding, sufficient fillet must be added carefully to secure strength at least equal to the original joint.

It will be noted that in Fig. 1 at (a) the fillet welding for tightness is simply a single bead carefully run so that it sinks in equally in both plates. This can be accomplished practically by the arc being drawn directly over the crack to be sealed with the electrode held pointing slightly more towards the upper or vertical surface, as gravity will take

Permission secured from the Electric Arc Cutting & Welding Co., Newark, N. J.

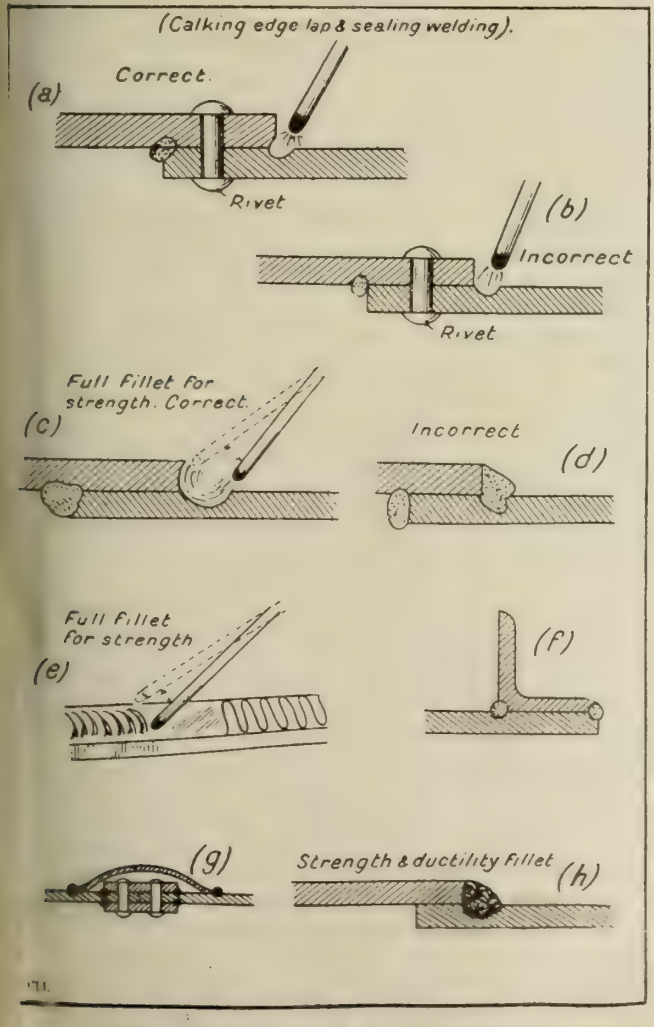

FIG. 1—EXAMPLES OF FILLET WELDING.

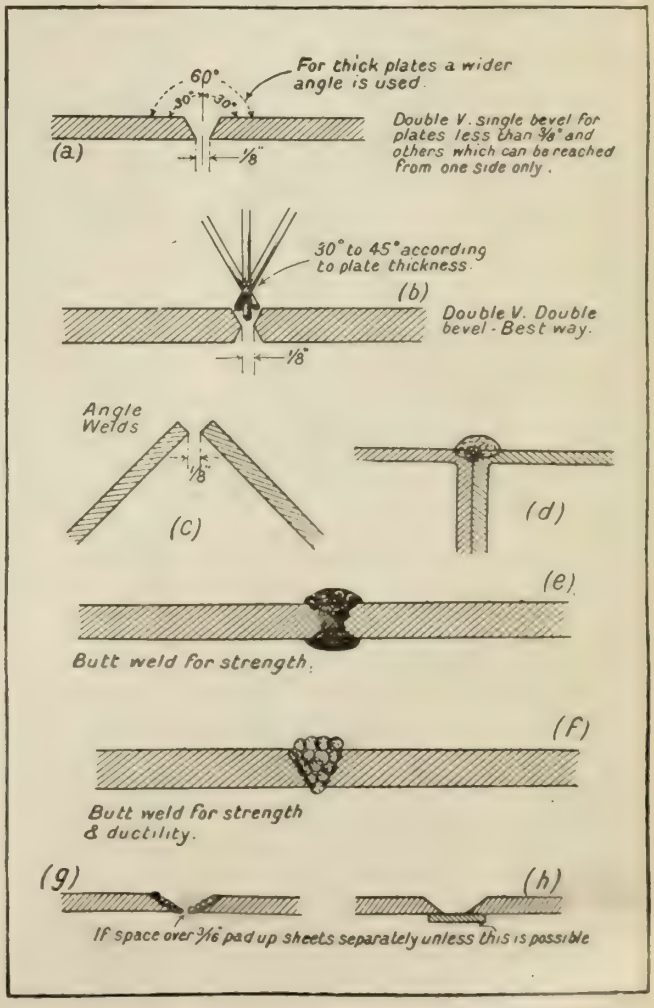

FIG. 2.—EXAMPLES OF BUTT WELDING.

care that enough metal from the electrode is deposited on the horizontal surface. If the electrode is held as shown in (b), i.e., somewhat exaggerated, of course, a beautiful weld may be made to the horizontal face, but none to the vertical face, thereby not sealing the joint although the weld may apparently be solidly against the vertical face. This comes from the arc not having been drawn from the vertical face and hence no crater having been made there, and although the electrode may have been pointed towards the face it simply runs down lying against it without welding.

Welds by Spreading

Fig. (C) shows fillet welds made by spreading, i.e., the electrode is moved back and forth either side of the crack so that the arc is forced to follow, forming a trough alternatively in the horizontal and vertical faces into which the electrode material is to be deposited. This method requires more skill than the single fillet, or a succession of single fillets, but, on the other hand, is quicker for full strength fillets. The most reliable way of all is to make one single bead as shown at (a) directly over the crack and then fill in for strength as shown at (c), advancing in such a manner that the bottom or horizontal part of the weld is always slightly in advance of the weld on the vertical face so that there is minimum danger of the molten metal running down and ahead of the arc. Fig. (e) shows how this should be accomplished by a side view.

Fig. (d) shows incorrect fillets with the metal overlapping, i.e., run ahead of the arc and with welds lying up against, but not fused into, the vertical face. Fig. (f) shows the manner of successive short beads necessary to obtain ductility in the weld. This method is necessarily slower and must be done more carefully, but where the weld is made up to resist bending strains, there is much greater chance of obtaining the necessary ductility than with the method shown at (c) although the combination method of (a) and (c) as described above, will give ductility of the sealing bead but not the second and final layer. In order to have the final layer reasonably ductile, even with the metal shown at (f) an additional layer should be added at generally a higher current value in order to anneal the entire mass. This additional layer for fillet welding must, in general be left in place, as it also adds additional strength, and whether the fillet is slightly larger makes no particular difference unless for jobs where fit is necessary, in which case it can be machined off. In machining a weld, sufficient annealing layer should be added so that as little as possible of the weld on which strength and ductility depend is to be removed.

The welding of boiler tubes after they have been rolled, beaded and often processed, is the most prevalent example of a single bead fillet for tightness only. Here the tube is secured in place to start with, even when a new tube is put into an old flue sheet, generally a ferrule of copper is put in between the new tube end and the old sheet to allow for the difference in size caused by the first or previous expansion. When a copper ferrule is properly applied, none of it sticks out beyond the bead, but even if irregular pieces do stick out the sealing weld can be made as usual, as a reasonable amount of copper fuses well with the steel of weld, bead and sheet. The proper cross section of the tube sealing bead should be egg-shaped with the large end welded in, and there is no need of chipping off the small protruding end, as experience has shown that no scale or soot results. In rolling and beading tubes, oil is used, and this oil must be burned out of the sheet so it is out from under the bead, or in welding the oil gas will bubble out through the weld, causing leaks and no job. The edge of the bead and flue sheet should be cleaned of scale by chipping or sand blast, the latter being the better, but not always available.

A heavy fillet, i.e., one that cannot be made in one bead, can be easiest and most reliably made by welding vertically from the bottom up, the bead into the two plates or surfaces of the fillet sides being welded first, following across the weld one layer behind the advance into the work surfaces. If the reverse method is followed there is danger of metal running down ahead of the puddle into the pocket of the V.

Butt Welding.

Butt welding, especially of plates, is the most satisfactory method, and in general is much stronger than lap welding unless with the possible exception of a joggled lap weld, i.e., one or both of the plates bent in lapping so that the weld is in the direct line of the pull or stress, which in the case of a joggled weld with one plate only joggled may be virtually a butt weld, with the additional overlap welded edge of the plate in which the jog is made.

Lap welds in general are not as strong as butt welds, because of the tearing and twisting strains due to the weld not being in the line of stress. A weld with additional plates such as the strap weld is stronger than a plain butt weld, but in fact, a butt weld is used as a foundation for strap welds. Riveting and welding where strength is the quality desired do not mix with advantageous results. For instance, one might expect that 50 per cent. strength could be made in a joint by riveting and the other half by welding, or that 50 per cent. of the strength could be made by spot welding and the remainder by arc welding. This assumption has been proved entirely erroneous, and an explanation is that in plates the joints are called upon to withstand the stresses one at a time, and that cases arise where the strains come on in a wave, so that the maximum at one point may be more than the factor of safety for half the strength of the plate, and would tear off different kinds of welds at 50 per cent. strength, like buttons on a coat, if the pull were on one at a time, whereas a direct pull coming against all the buttons would be withstood, and could be relied upon for the figured strength. In other words, the riveted joint must be considered at its strength and the spot or arc welded joint at its strength, and the strength of the joint be considered as the strength of the maximum, but not the strength of their addition.

In making a butt weld better results can be had by double bevel double "V" as shown at (b) Fig. 2, but where the plate is not unduly large, i.e., less than one half-inch, but where access for welding can be had only from one side, the single bevel and double "V" is almost as desirable. For work thicker than half inch the single "V" has to be widened out to such an angle that the electrode can be added with assurance at the bottom of the "V" so that the amount of metal to be added is from two to three times as much as with the double "V". Geometrically, a single "V" is twice the area of a double "V," but in welding this ratio is not exactly borne out because in both the single and double "V" the butt edges are left slightly apart and this reacts more to the advantage of the single "V" than the double "V"; however, as explained above, due to depth of the opening the single "V" requires more metal to be added, takes longer, less chance to make a perfect weld and internal strains, if any, not balanced. In other words, if a single "V" weld of any appreciable thickness is made lying flat the ends of the plate will turn up like the wings of a bird. If the plate is held down there will be a strain in the weld of the adjacent steel, and if this strain is less than the ult strength, the steel will take it up; if not, a crack will result either in the weld or the adjacent steel The double "V" offers the solution of balancing these strains, especially if the weld is not made all at one time or one side, i.e., run the first bead on each side and then fill in on the side opposite to the second bead run. On large work two men sometimes work on a double "V," one at each side.

Double "V" Weld

The double "V" weld has the advantage of the great liability of the metal falling through the abutting edges and as is well known, where no weld is made the metal is necessarily burnt because there has been no means for conducting the heat into the plate and lowering the massed temperature to the desired point for welding. If the correct heat adjustment of the machine was made for the metal to be burned from falling free there would never be a large enough crater in the parent metal to make a weld. Any metal thus falling through a double "V," if not cleaned out before the bead on the side is started, will exist as burned metal, or is liable to exist as slag due to the heat of the second bead completely devitalizing both the metal fallen through from the first bead and the new metal of the second bead because the burnt metal of the first bead will not conduct away the heat which is required in welding into the parent metal. This is gone into in detail to show that on imperfectly joined work, if the metal appears protruding it must be stripped off.

(Continued on page 53.)

What Causes Explosions in Air Compressors?

Effect of Cylinder Wall Temperature—Dust and Carbon—Carbonization of the Oil—Ignition of the Carbon—Removal of Carbon and Oil Deposit—Air Valves Should be Cleaned.

*By A. D. RISTEEN.

MANY who have speculated on air-compressor explosions have attributed them to the ignition of il vapor. The air in the compressor cylder has a rather high temperature uring a part of each cycle in conseuence of the heat developed by comession. In an ordinary air compressor ith tight valves the theoretical limit of mperature might be somewhere about 0 or 700 deg. F. if the compression ok place without any loss of heat. ctually, however, there is a considerle cooling action on account of water ckets and intercoolers, so that the aximum temperature should not exed something like 400 degrees.

It has been maintained that lubricatg oil is likely to give off an inflamble vapor at this temperature, which, en mixed with the air in the comessor, is capable of exploding. Some the opponents of this theory have, wever, confidently stated that explons occur in connection with high sh-point oils even oftener than they in conection with those having low sh points.

ffect of Cylinder Wall Temperature.

Most of the oil that is present in a mpressor cylinder is lodged on the lls of the cylinder, and owing to the oximity of the water in the cooling j'kets these walls do not have a temp'ature anywhere near as high as the a in the middle of the cylinder. Under gd operating conditions and with welldigned apparatus the inner surface of tl cylinder wall is probably not much nre than 50 deg. F. hotter than the naximum temperature of the jacket w er. If this is so it follows that the o that is adhering to the cylinder is n giving off any significant amount of lammable vapor, because the greater pt of it is adhering to the comparatily cool metal.

ome of the oil will be lodged on the to of the piston, and this may be hot enough to give off a certain amount of inammable vapor if the flash point of th oil is lower than the maximum temperature of the air in the cylinder. It is nportant, however, to note that unde normal working conditions the air in the cylinder is comparatively cool during the greater part of every cycle, the high temperature being attained only toward the end of the compression stroke. Hence, the total evaporation of oil from the faces of the piston will be far smaller than the advocates of the oil-vapor theory have probably assumed.

Oil spray in the cylinder or connections is sometimes suggested as a source of explosive action. It is hard to understand how spray could be formed from oil that has once adhered to the metal walls, except in consequence of the rupture of some part of the apparatus; any spray of this kind that does not immediately lodge on the walls is swept out into the receiver with the next discharge from the compressor; and moreover the amount of such oil spray would be so small that any explosion that it might produce would not even be noticeable.

Dust and "Carbon."

We come, now, to the consideration of such combustible solid matter as may be present in the cylinder or its connections; and here we are encountering a far more serious item. The free solid matter that is found in the cylinders, piping and receiver of air compressors is of two general kinds. First, it contains whatever may have been introduced into the air compressor in solid form; for example, dust drawn in through the intake. The dust held in suspension by the air that is taken into the compressor usually contains more or less mineral matter, which is likely to be either sandy or clay-like. Such matter is incombustible and probably would not be directly harmful except as it may increase the friction and the wear. But the incoming air may also contain combustible material, and this must be reckoned with. The combustible matter may be of an organic nature, or it may consist largely of particles of carbon. This last condition is most likely to prevail when the intake of the compressor is near a coal pile, or where it can take in more or less smoke from a chimney or stack.

"Carbonization" of the Oil.

The other source of solid matter in the cylinder or receiver or connections is the so-called "carbonization" of the oil itself. We speak of solid deposits of this nature as "carbon," but although they contain free carbon they consist largely of oil in various stages of disintegration, and of compounds formed from the oil under the influence of heat and the oxygen of the air.

Carbonization is due in large measure to the use of improper oil or of an excessive amount of it. The oil should have such a composition that it is reasonably stable at the temperatures that are likely to occur in the compressor or its connections; and this means, among other things, that it should not contain any animal or vegetable constituents, but should be purely mineral. Any oil will undergo a certain amount of decomposition, however, under the conditions to which it is exposed in air-compression apparatus. Slow oxidation is favored by the fact that the oil is spread out in a thin layer and exposed to heated air. Moreover, at the temperatures that prevail in the apparatus the oil is likely to "crack" to some extent. That is, it is likely to break down slowly with the formation of somewhat lighter oils and the simultaneous liberation of a certain amount of free carbon.

No oil that is worth even momentary consideration contains, in its original state, any free carbon; and the percentage of carbon present in the oil (in combination with hydrogen) is no criterion whatsoever of the likelihood of the oil to deposit carbon. The carbon deposits thrown down by paraffin-base oils are said to be hard, gritty and specially adhesive, while those that are derived from asphaltic-base oils are

OIL USED IS IMPORTANT

Carbonization is due in large measure to the use of improper oil, or of an excessive amount of it. The oil used should not contain any animal or vegetable constituent, but should be purely mineral. No oil that is worth even momentary consideration contains, in its original state, any free carbon; and the percentage of carbon present in the oil (in combination with hydrogen) is no criterion whatsoever of the likelihood of the oil to deposit carbon.

Any oil that gives a considerable deposit of so-called carbon is objectionable in connection with air compressor lubrication, whatever the nature of the deposit.

* he author is connected with the Travellers In-ance Co., and presented this article before th Engineering Section of the National Safety Co cil at Philadelphia.

described as fluffy and easily removable. However that may be it is certain that any oil that gives a considerable deposit of so-called carbon is objectionable in connection with air-compressor lubrication whatever the nature of the deposit.

Ignition of the Carbon.

It is well known that these "carbon" deposits take fire at times, and this can hardly be due to the air in the compressor attaining a temperature high enough to ignite pure carbon, especially when the carbon is in compact form.

It is not unlikely that the free carbon that is present in the deposits occasionally acts as a catalyzer, in promoting the rapid oxidation of the oily matter with which it is associated. Catalysis plays an important part in modern chemical manufacturing, and we are enabled by means of it to bring about many chemical reactions that will not occur unless a suitable catalytic agent is present. Charcoal and coke are among the substances used in this way to promote certain chemical actions; and perhaps it is not unreasonable to assume that the carbon in a compressor or its connections may sometimes induce rapid oxidation of the oily matter. It is known, too, that some of the products that would be formed in this way are themselves capable of acting as catalyzers, so that they might accelerate the action when it had once become well started. Fine metallic particles, worn off from the cylinder or the piston, are sometimes present in the deposit, and iron oxide often occurs to a significant extent, both being active catalyzers under certain conditions.

The heat generated by the beginnings of the oxidation would facilitate further action, and so the thing would go on until presently we might have a glowing or burning mass. This in itself might precipitate an explosion by heating the metal walls so that they could no longer withstand the normal air pressure to which they are subjected. Furthermore, the carbon deposit, if it happens to be of a light and fluffy nature, may be disturbed so that we have what is in effect a dust explosion, the finely divided carbon playing the part of the dust and the ignition taking place in consequence of the catalytic firing of the oily matter in the manner described.

Hard carbon deposits often prevent the valves of a compressor from closing properly, and this is likely to cause serious overheating. The piston, in making its return stroke to fill the cylinder with a fresh charge of air, will be followed by a certain amount of the compressed and therefore heated air, flowing back through the leaky valves from the receiver and its connections. Under these circumstances the contents of the cylinder are already, and before the compression begins, at a temperature considerably higher than that of the surrounding atmosphere; and this means that when the next compression stroke is completed the temperature in the cylinder may be a good deal higher than it would be if the valves were tight. The increase in temperature produced in this way and also by the friction of the air in churning back and forth through the restricted valve opening naturally accelerates any tendency toward the production of fire and is, therefore, a serious matter.

Removal of Carbon and Oil Deposits.

Every effort should be made to prevent the accumulation of "carbon" deposits anywhere about the compression apparatus, and such matter as may be deposited in spite of all reasonable precautions should be cleaned away, frequently and regularly. A good deal can be accomplished in the way of cleaning the compression apparatus by discontinuing the oil from time to time and feeding soapy water into the cylinder for two or three hours—say once a week. The solution may be made up of one pound of soft soap to seven or eight quarts of water, and it is advisable to feed it into the cylinders at something like ten times the rate at which the oil is ordinarily supplied. The frequency with which this treatment should be given depends upon the experience with the particular air compressor under consideration.

Some authorities recommend the introduction of a solution of lye into the pipe between the cylinder and the receiver every month or two. The lye solution may be made up by using one pound of lye to eight or ten quarts of water, and it may be delivered into the air discharge pipe by means of a sight-feed lubricator at the rate of 60 to 70 drops per minute. After using the lye or the soap solution the receiver should be blown off, and oil should again be used in the cylinder for a time before stopping the compressor. Otherwise rusting is likely to occur.

When hard carbon deposits form which are not removable by the treatment here suggested, they should be cleaned out by whatever means may suggest itself as most effective. For instance the air valves should be removed whenever necessary and cleaned by mechanical means. No kerosene or other inflammable solvent should be introduced with the air, however. This practice which is far from unknown, is exceedingly dangerous.

HOW TO GET RID OF RUST ON IRON OR STEEL BEFORE ELECTRO-PLATING

By RALPH H. BUTZ

In the electroplating of iron and steel it is always necessary to clean the surface from grease, oil, rust and other foreign matter previous to plating, otherwise, of course, the deposit will not adhere to it. The cleaning of the surface leaves a chemically clean surface and one which is in the ideal condition for rusting. It is not uncommon to find a plater who will carefully clean rust from an iron or steel surface for the purpose of plating it, and then, before the actual plating operation takes place, unknowingly allow it to rust again.

After pickling or cleaning off the grease or other foreign matter, the plating operation will be satisfactory if the article is carried, after being rinsed, directly to the plating tank, as it then will not have an opportunity to rust; but if it is allowed to remain some time, as it is usually required to do, before plating, then trouble usually commences.

Iron or steel which has been cleaned and is ready for plating should never be allowed to dry, if possible. If it is allowed to dry, then it will invariably rust. As it is always impossible, however, to plate the articles immediately after cleaning, and they must remain for some time previous to this operation, then some process is necessary to prevent rusting during such interval.

Clean surfaces of iron or steel ma be prevented from rusting by immersio in an alkaline solution of some natur It does not matter just what this alka line solution is, but it must be strongl alkaline. Among the substances tha can be employed are: Sodium carbo ate, sodium bicarbonate, potassium ca bonate, caustic potash, caustic soda c lime. These substances, of cours should be dissolved in water. The on which is most satisfactory is sodiu carbonate (carbonate of soda or sa soda). This is cheap and readily di solves in water. Lime water can be use but is not as good as sodium carbona for the reason that it is apt to leave film of carbonate of lime on the wor and this must afterwards be remove with weak acid. The sodium carbona is the best substance for the purpos

Editor's note:—At present there a several preparations on the market th claim not only to cleanse the parts, b protect them from rust. Recently w were privileged to watch a demonstr tion of such a compound, and the par dipped were not only allowed to dry, b were left for some considerable tim without any sign of rust. Rust can likened to one rotten apple in a barr of good apples. Once let it get a sta and it will go through the whole barr

WHAT OUR READERS THINK AND DO

SCREW CUTTING QUERY

(Answered by J. Davies)

I notice a screw cutting query in the May 5th issue by J. H. R. The following is my solution:

$$\frac{9.875 \text{ inches}}{6 \text{ inches}} = \text{Pitch to be cut.}$$

$$\frac{1 \text{ inch}}{4 \text{ threads}} = \text{Pitch of the lead screw.}$$

$$\text{Thread ratio} = \frac{9.875 \times 4}{6 \times 1} = \frac{39.5}{6}$$

$$= \frac{79}{12} \text{ gears required.}$$

We will next proceed to compound the gears; as 79 is a prime number and cannot be divided or factorized, it is impossible to cut this pitch without a 79 gear. The gears required would be 79-75—45-20, the first two being the driving and the last two the driven gears. This gives 79 revolutions of the lead screw to 12 revolutions of the work. In order to put the nut in at the right place for each cut it would be necessary to reverse the lathe or measure off 19¾ inches (79 divided by 4) on the lathe bed. The nearest approximation with the gears available in the given set would be

$$\frac{13 \times 6}{2 \times 6} \text{ or } \frac{78}{12} \text{ instead of } \frac{79}{12}$$

This would mean 65 into 30 and 60 into 20, and the actual pitch cut with such gears would be $6.5 \times .25 = 1.625$ inches, an error of twenty thousandths per thread.

SCREW CUTTING QUERY

(Answered by J. McL.)

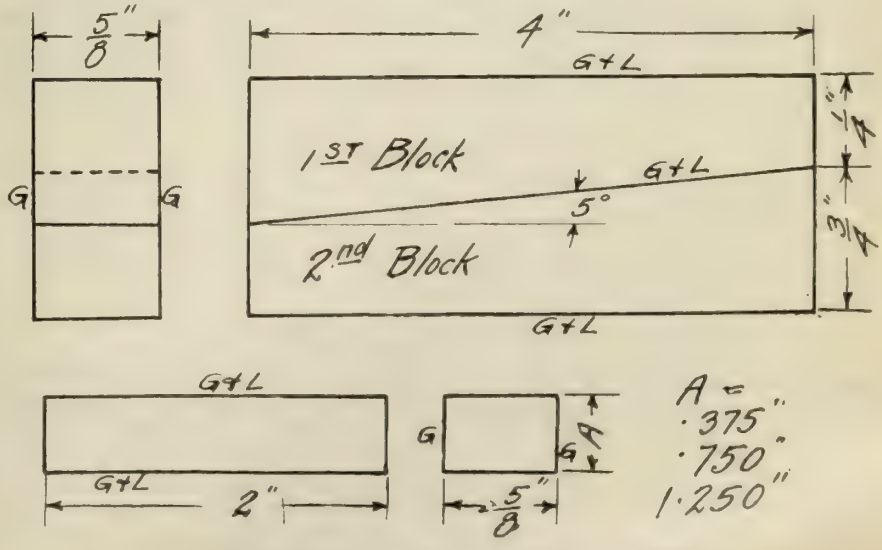
The necessary gears can always be arrived at by the simple method of multiplying the decimal pitch by any number that will give an even number of inches. Multiply this number by the number of threads per inch on the lead screw and thus obtain the desired ratio for the gears. In the example stated, the pitch of the work screw is 1.6458 inches, and this multiplied by 48 gives 78.998 inches. Taking 79 as the resultant (an error of .002 in 79) the threads of the lead screw in the same length would be 79×4 equals 316 threads. The desired ratio then would be 316 to 48. However, gears with teeth of these numbers are not available, so it is necessary to obtain the same ratio by compounding the train. By the simple process of cancellation this can be done. Multiplying each term of a ratio by the same number does not alter its value.

To prove the accuracy of this statement, multiply the teeth in the driving gears by the pitch of the lead screw, and divide the product by the teeth in the driven gears, thus:

$$\frac{79 \times 75 \times .25}{20 \times 45} = 1.6458 \text{ inches.}$$

SCREW CUTTING QUERY

(Answered By S. Leeman)



From the nature of the "screw cutting query" in the May 5th issue of Canadian Machinery, it would appear as though the piece might be a troublesome one to handle, if done in the ordinary way on the lathe, and if these are required in quantities it might be advisable to rig up a separately driven end mill of the proper angle, instead of the single pointed lathe tool. As the gearing is obtained from the relative pitches of the work and the lead screw, or 6 turns of the spindle to 39½ turns of the 4-thread lead screw, gears of a like ratio are required. As it is impossible to use gears with 6 or 39½ teeth, we try doubling them, giving 12 and 79, but as 20 is the smallest gear in the given set, we use it in place of the 12. This slows down the lead screw 3-5 of the required number of revolutions, but by using the 50 and the 30 gears—both of which are included in the set—on the intermediate stud we can overcome this. The gear train, starting from the spindle, would then be, 79 into 30 and 50 into 20; the 79 being the new gear to make. If an 80 gear was used instead of the 79 there would be an error of about one-eighth inch in 6 turns of the spindle.

SLIDING PARALLELS.

By GEORGE R. BROOKS

The sketch shows a set of sliding parallels that are inexpensive, yet save both time and money. They eliminate making a master check with each different size of snap gauge, and the beauty of it is, that any gauge maker can make them.

I made mine from Jessop's tool steel, this showing about 80 on the scleroscope. The angle surfaces should be lapped to wring together, and the

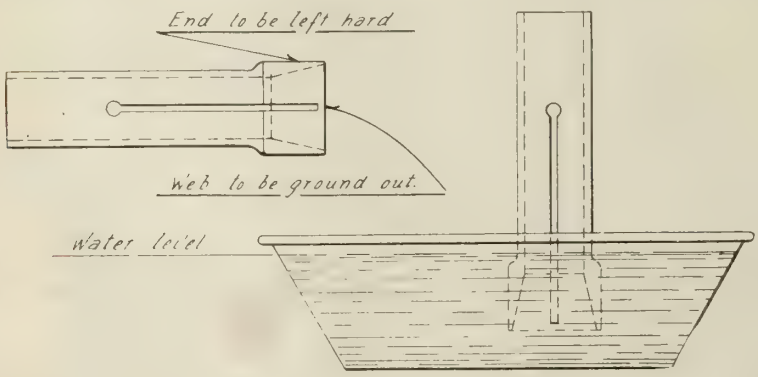
SHOWING HOW THE PARALLEL BLOCKS ARE USED.

straight sides should be ground and lapped parallel. The parallels will give a range of ⅝ in. to 1⅜ in., and the three additional blocks ⅜ in., ¾ in., and 1¼ in., will give a range sufficient to cover the majority of small snap gauges. Of course additional blocks can be made for any larger size required. An accuracy of .0001 in. can be maintained with these parallels.

SCREW CUTTING QUERY

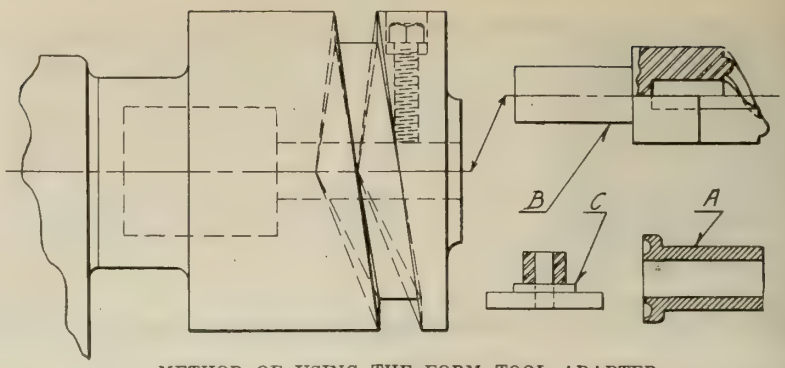
(Answered by R. H. Hicks)

Regarding the screw query by J. H. R. in the May 5th issue. The thread ratio is 1.6458 inches divided by .25, or 6.5832. To obtain the greatest accuracy have a new gear made with 66 teeth and use the train 66-40—80-20. This will give a ratio of 6.5999, which is very close to that of the required ratio of 6.5832.



HARDENING DRAW-IN COLLETS.

By C. E. H.



Having several small draw-in collets to make which were to be left very hard at the end, and being a cheap job which was not to be ground afterwards, the following method was adopted by the writer, and good results obtained without any trace of distortion. The collets which were less than 1/32" in the walls, and about 1½" long, as shown in sketch, had three slots milled lengthwise 1" in length. They were bored and turned to size, and the slots milled within about 1/32" or less from the top edge.

They were then heated and quenched in oil, nose downwards and perpendicular to the surface of the oil bath. They were then drawn with a torch to a spring-temper from the back end, with the nose (to be left hard) just held below the surface of a dish of water. The small webs left at the end of the slots were then ground out with a small carborundum wheel about 1" dia. and 1/32" thick, held in a small dental hand-piece.

While the hand-piece may not be available in the average shop, the small wheels with suitable arbors may be had at any dental supply house for a few cents, and can be held in the lathe chuck with fair results, but the high speed necessary for such small diameters is lacking.

HOW THE DRAW IN COLLETS WERE HARDENED.

METHOD OF USING THE FORM TOOL ADAPTER.

Just in passing it might be well to mention that the small cost of a flexible shaft and hand-piece and small motor, with the many handy little attachments such as burrs, polishing bucs, points, brushes and small grinding wheels, (which are obtainable in every conceivable shape and size) will be offset in a few weeks in the time saved on the hundred and one little jobs which can be done in a few minutes, which would take an hour or more if done by hand or other inconvenient methods.

This handy equipment has to be used but once to be appreciated; and in the machine shop where they do the finer class of repair work its value is inestimable.

Some time ago the travelling mechanic for an adding machine company was in town, and he had with him a small hardened cam which was to go to make a repair he had in hand. It was an odd-shaped thing and did not quite fit; and had to have a little ground out of an out-of-the way corner. Well he "peddled" it around to several machine shops but they could not touch it, as it was too small for their equipment. The last place he went to was a shop who did out heavier work, and they sent him to us. The manager brought him to the writer to see if we could help him out. He looked devoid of hope and was positively leg-weary; but when we did his little job with the ever-ready handpiece in two minutes, using a small wheel about ¼" dia. and 1/32" thick he became quite enthusiastic and has since paid us two visits with similar "bugbears."

I mention this at length to illustrate the extreme usefulness of a tool which until quite recently, has only been looked upon as an instrument of torture when the dentist says sweetly "open please."

FORM TOOL ADAPTER

When form tools are required that do face forming, and are to be ground without changing their form, an adapter made to fit the lathe spindle can be used to advantage. This adapter is bored out to fit the shank of the forming tool and on the outside is a cam slot running around with the necessary amount of lead to give sufficient clearance on the tool (b). The tool blank is first made up and then a quarter of the land is milled away so as to permit the tool to withdraw when making the cuts to form it. The carriage of the lathe (one that the pinion can be withdrawn from the rack so as to permit easy travel) is connected to the cam by the strap (c) which is fastened across the carriage. On this strap is a hardened stud and roller. The product of this type of form tool is shown at (a). Owing to the peculiar shape of the form tool, care should be taken in its hardening.

NEW ZINC ALLOY.

A new zinc alloy for bearings is discussed by Heinrich Falkenberg in "Metall und Erz." According to an abstract in "Technical Review," it is known that an alloy consisting of iron 1.6, zinc 94.9 and lead 3.5% is a mixture very suitable for bearings. The production of this alloy requires a melting temperature of 405° C. The product has a crushing strength of 1,740 kilogs. to the square centimetre. Futher investigations have shown that a higher temperature, up to 1,000° C., and a corresponding increase in the iron content up to 3%, give a greater resistance to compression strains—namely, 1,620 kilogs. The process of producing this alloy is as follows: In a graphite crucible, 6.5 parts of hard zinc are melted with 3 parts of iron at a temperature of 1,000° C., well stirred and the dross removed. To this bath, 3.5 parts lead are added.

Heat in Bearings

CLAIMING that the heat in a bearing is not the cause of fear, C. H. Norton, in Mechanical Engineering, comments as follows:—

"The bugbear of mechanics has always been hot bearings. We have tried to develop bearings that would work without generating any heat at all.

"I conducted some experiments with a pair of journals running in half boxes with the upper side of the journal exposed. A recess on the leading side of the journal was made in the box to receive the oil and the corner was rounded to induce oil to flow between the journal and the box. This recess was filled with a heavy oil which rolled under the journal and remained upon it when it was slowly turned. As its speed was increased, oil was left in the recess until at a speed of 1,000 feet a minute on the journal periphery nearly all of it was scraped off into the recess. Even at this speed there was enough left on the journal so that it did not abrade the metal. Though the temperature was so high that it would burn the flesh the journal continued to run uninjured.

"The heavy oil was wiped off, kerosene was placed in the recess, and a similar test was made. At high speed the kerosene appeared to remain on the journal and it revolved practically cold through quite a long period.

"Next an ordinary machine oil was placed in the recess and the journal revolved as before. At high speed part of this oil was scraped off into the recess. Some heating was developed, but not enough to burn the flesh and the heat did not increase above the original point.

"In the fourth test a universal spindle oil was used, which remained on the journal at all speeds. So little heat was generated that it was just barely warm, regardless of the length of time it ran.

"These experiments tend to show the correctness of the report on lubrication made by Lieut. G. S. Bryan, of the United States Navy, in which he said, 'The first effect of a high temperature in a bearing is to thin the oil. The effect of cooling the bearing is to increase the friction. There is no virtue in keeping a bearing at a low temperature by the use of a considerable amount of cooling water, and there is no reason why it should not be run at a high temperature as long as it is in good condition and is getting plenty of good clean oil.'

"My thought in connection with this is that we have been deceived into a state of fear because there is heat in a journal. Any journal that will revolve long enough without abrasion to allow us to manifest this fear and worry, I consider to be perfectly safe."

Speeds of Grinding Wheels

SPEAKING on the subject of "The Speeds of Grinding Wheels," W. T. Montague in Grits and Grinds, brings out some valuable points. He says that in general a soft grinding wheel revolving rapidly permits a higher production than a hard wheel revolving more slowly.

This is true, he states, because the more open structure of the soft wheel provides greater clearance for the grinding chips, which results in a freer and cooler cutting action. Theoretically, therefore, the correct speed for grinding wheels is the safe maximum speed at which the wheel may be operated. In actual practice, however, certain ranges of peripheral speed have been found to give good results on certain classes of ground work. For example, a satisfactory wheel speed for sharpening wood-planer knives is around 3,500 surface feet per minute; for off-hand snagging of castings, 5,500 surface feet per minute; for cylindrical grinding of crankshaft pins and bearings, around 6,000 surface feet per minute; and for cutting off hardened and high-speed steel, tubing, and the like, the proper speed approximates 9,000 or 10,000 surface feet per minute.

In surface grinding, lower wheel speeds are used than for cylindrical grinding, because mechanical limitations usually prevent the work-table being traversed fast enough to keep the wheel face opened up and free-cutting; but, generally speaking, certain grits and grades of grinding wheels operating under these speed conditions have given satisfactory results.

It is generally thought that the faster a grinding wheel revolves, the greater its productivity in a given time. This is not altogether true in precision operations, as in cylindrical grinding for instance. It is only true to a limited extent in off-hand grinding, such as the snagging of castings. In cylindrical grinding, the production of a given wheel is determined by the depth of cut, the table traverse, and the diameter of the work. Hence, the controlling and limiting factors are the rigidity and general sturdiness of the grinding machine to permit deep cuts, and the traverse speeds of the table or wheel, if the wheel-head travels instead of the work-table. Increase of wheel speed in cylindrical grinding changes the size and shape of the chips. The rate of production is not greatly affected, unless the higher speed permits the use of a softer wheel, which might cut more freely. But for a given wheel there is no difference in production, whether 4,500 or 6,500 surface feet per minute is used, provided the grade or the work speed is adjusted to these different wheel speeds.

He then speaks on off-hand grinding, after which he draws the following conclusions:—

1. The grade of hardness to be recommended for a grinding operation depends on the surface speed of the wheel.

2. The grinding wheel should be as soft as is feasible for the operation, and whenever possible operated at the high end of the recommended range of speeds.

3. For a given wheel used for precision grinding operations, not much increase in production is to be expected from increasing the speed of the wheel alone.

4. The logical way to increase production in precision grinding operations is to increase the traverse of the work past the wheel or the depth of cut of the wheel.

Self-Lubricating Bearings

A NEW bearing material which is a mixture of graphite and high grade synthetic bronze, and which has self-lubricating qualities of a high order, has recently been developed in the G. E. Research Laboratory following successful tests under service conditions. Perfection of this material—genelite—came after research extending over a period of several years.

The new material, says Scientific American, contains graphite amounting to 40 per cent by volume of the whole mass. Tests have shown a high degree of porosity, the metal being able to absorb as much as 2½ per cent by weight of oil. Another characteristic is that the bearing never siezes or freezes, that is, the metals of the shaft and the bearing never flow or weld together. If a bearing sticks, owing to too close a fit, all that is necessary is to reassemble it with the proper fit, no damage being done to the shaft or bearing.

Among the self-lubricating uses for the new bearing are brake-rod bushings, clutch-centering bushings, throttle control, fan and pump shaft bushings, where such material saves much trouble and expense of overhauling and repair. On the main engine genelite has proved useful for places such as main bearings, crank-pin bearings and piston-pin bushings, which are supposed to be well lubricated at all times, but where wear is likely to be excessive. The metallic component of the new bearings is made from the oxides of tin, lead, and copper, composing a high grade bronze, all the materials being in a finely divided state. Graphite is added in sufficient excess quantity to reduce the oxides to the metals, and leave the required graphite content in the finished material.

The mixture, still in powdered form, is then pressed as nearly as possible to the required shape in massive metal molds. In this pressed form it will not stand much rough handling, so it is given a final bake, which sinters the metals together into a homogeneous bronze, holding the graphite uniformly distributed throughout its mass. Baking clamps the graphite particles securely within the mass of bronze so they cannot be washed out or detached save by dissolving away the surrounding metal with acids.

Suggestion Dont's

THE General Electric Co., Schenectady Works, used their shop paper to good advantage recently to help employees who were offering suggestions. They issued a series of "Dont's" which aided the employees generally in sending in more complete ideas for perusual. Here are the "Dont's" that were published:

"Don't make suggestions of a general nature without giving instances of how and where same may be applied.

"Don't get the idea that your foreman will be 'sore' because you make suggestions. The average foreman in this plant is a 'regular fellow,' and is usually glad to help you get your suggestions into shape for submission.

"Don't forget to put your building and check number on the suggestion blank.

"Don't forget to give drawing and part numbers and also the name of the apparatus to which the suggestion applies. This is of great help to us in investigating the suggestion.

"Don't forget that even a rough sketch is of great help in making your suggestion clear."

Prevention of Accidents

THE prevention of accidents in the various branches of the petroleum industry differs but little from accident preventions in any other industry in this country. Though there are some hazards in this business which are peculiar to it, most personal injuries result from general causes, such as the men falling, being struck by falling objects, and injured in the use of hand tools.

In analyzing the reports of 1,000 accidents in this industry, continues C. L. Turner in Petroleum Magazine, it was found that over 31 per cent. were due to the workers being struck by falling objects; 10 per cent. were caused by the improper use of hand tools; nearly 9 per cent. by men falling or tripping; and about 8 per cent. by the men being struck by passing objects. Injuries by stepping on nails caused 4 per cent. of the accidents.

Thus, about 62 per cent. of the accidents reported were caused by the fact that the workmen had not fully acquired the safety habit. Very few of these accidents could have been prevented by any engineering revision.

Many accidents in the production division of the industry could be avoided by properly instructing the workmen and by the issuance and posting of notices showing the methods of procedure in the different processes where accidents are likely to occur.

Unguarded belts and shafting are always a source of danger and should be avoided wherever possible. Thorough and complete inspection of motor trucks at regular intervals, and care in the selection of drivers will materially reduce the accident hazard in the automotive branch of the industry.

The latest airplane journey of importance, that of the trip to Fort Norman, a distance of nearly 1,600 miles by airplane, has been completed in safety. This is one case where there is not the slightest suggestion of stunt. The main idea was SPEED. The Imperial Oil Co. wanted a party to arrive at their new oil fields as quickly as possible and the airplane was used as the best method available. It is significant that while the journey by airplane was exceedingly fast, the return journey by water took almost a month.

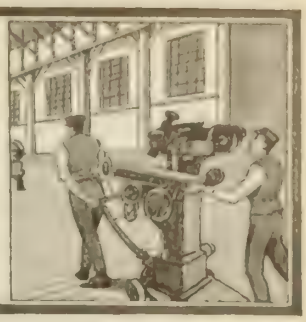
Selling the Sales Force

SPEAKING of a recent strike that the S. F. Bowser & Co., Inc., Fort Wayne, Ind., experienced, Frank H. Williams, who is an industrial consultant, states in Industrial Management, that as a result of the strike the plant lost 800 workers. He continues in the following strain:

The strike was broken, but,—and this is the interesting thing about the new workers,—in order to fill the 800 vacant places, over 4,000 men were employed at one time or another. In other words only one man in five measured up to the necessary qualifications.

Without going into details as to just what tests the company went through in order to pick its workers, it is interesting to know that one of the things the company did with these new employees was to "sell" them the sales organization. And in this selling of a concern's sales organization of the factory workers is a thought which might be made use of to good advantage by other plants.

Isn't it a fact that in many plants the factory workers have very ittle conception of just what the sales organization means to them? Isn't it a fact that many factory workers give the sales organization mighty little credit for the company's success and in fact, think of the salesman only as "guys" with a soft job, and the chance to dress up with white collars every day? And isn't it a fact that a better understanding on the part of the factory workers that without an efficient sales organization there would be no work for the factory, would tend to make the workers more respectful of company management and less inclined to feel that they are the whole works?



A Successful Experiment.

In the case of the Bowser company the effort to sell the sales force to the factory workers met with signal success. At the annual convention of salesmen held at the company's plant during the summer and attended by several hundred of the leading members of the sales force from every state in the union, a special effort was made to establish a co-operative point of contact between the salesmen and the workers. The salesmen were sent into the factory and were given in charge of specific workers who showed the salesmen around and explained to them just what the factory was doing. The salesmen, in turn, became chummy with the workers and told about some of the difficulties experienced on the road and finally, the salesmen gave badges to those workers who took them around the shop.

All of this was an eye-opener for the workers. Most of the workers had known practically nothing about the operations of the salespeople and it came as a considerable surprise to learn how hard the salespeople worked and how important they were in keeping the factory in operation. And that this all operated to create a splendid feeling among the new workers was attested in more ways than one.

DEVELOPMENTS IN SHOP EQUIPMENT

PRECISION DRAFTING INSTRUMENT.

E. Lawrence, 2533 McClellan Ave., Detroit, Mich., has developed a drafting compass that is intended for precision work, or for general use on the drafting board. The instrument is intended for the drawing of circles from 1/16 to 12 in., and by the use of an extension bar circles up to 24 in. diameter can be drawn. Plain points are provided, these being inserted in both arms of the instrument when using it as dividers.

The principal feature is the fact that the two legs are always parallel, or normal to the plane of working, hence the name, "Normal Precision Drafting Instrument." Because of this fact, the centers of circles being described are not gouged out, as frequently occurs when the points strike the paper at an angle. The instrument can be quickly set to the radius desired, and is then readily clamped in position, so that the radius will not change while the circle is being described.

The inventor claims that there is no back-lash or shake in the joints, as all of the pivots are of conic construction, made of steel and hardened and ground. The tightness of the joints may be adjusted by means of lock nuts. The grip is of large size and is made of aluminum, while the working parts are made of steel, tool steel being used for some parts and mild steel for others. The arms are rust-proofed by either of two methods. The first is the Parker process, which makes the arms jet-black; the second is by electro-sherardizing, by which process a coating of zinc is amalgamated with the steel, leaving the instrument gray in color.

SPOT-WELDING MACHINES

The Taylor Welding Company, of Warren, Ohio, are now manufacturing a welding machine for spot welding pieces of sheet steel from 1-64 to ⅛ inch thick. The machine may be operated either by hand or foot. Duration of contact is controlled by means of automatic switches. And control of the welding process is obtained by means of a button in the end of the hand lever. Adjustment can be made for seven different travels for the hand lever and the foot treadle. Pressure on the work is also adjustable. Water circulation is provided through both electrodes.

CYLINDER RE-BORING MACHINE

The Central City Machine & Tool Co., Syracuse, N.Y., have developed a reboring machine which is said to be able to rebore motor car engine cylinders without taking the engine out of the car. The machine is self contained and is provided with three bronze bearings supporting a boring-bar. These bearings are split to take up wear and keep the machine in perfect alignment. The boring-bar is driven by a worm-gear that insures a uniform drive from the motor, which is of ¼ horsepower capacity and may be provided for alternating or direct current.

Three cutter-heads are furnished for cylinders from 2¾ to 4½ inches bore, and they are constructed with a cam adjustment that gives a smooth equal movement. The four inserted cutters are placed opposite each other, and revolve on the boring-bar, which is accurately centred. This construction equalizes the pressure of the cutters during the entire operation. The cutters are made of "Rex AA" high-speed tool steel. The machine is the invention of L. S. Keeler of the above mentioned company.

TAP AND DISC HOLDER

The Warner & Swazey Co., Cleveland, Ohio, have patented and produced a new clutch tap and disc holder. Instead of 23 parts, which there was in the old type, the new holder has only eight, and it will hold either right or left hand dies or taps. To change from right to left a screw driver is all that is necessary..

The only difference in the tool when used for right, and when used for left hand work is the position of the pawl. To change from one to the other, the pawl is turned half way around in its hole. A small pin holds the pawl in the position placed. When threading, the pawl holds the tool rigid, by a metal to metal contact, until the turret stop is reached. Then the head moves forward on the work, pulls the cam over the pawl which releases the head, allowing it to revolve freely. The spring cushions the pawl so that the release is without jar and practically noiseless. The material in each part has been carefully selected and especially treated to stand up under the work required of it.

Is A Purchasing Agent Essential?

SPEAKING of the value of purchasing agents a few days ago, we were surprised to hear a certain manufacturer say that he wouldn't give such an individual house room. To our mind the purchasing agent is somewhat like the Englishman, as portrayed upon the vaudeville stage, the butt of many a joke he doesn't deserve. There are good and bad purchasing agents, and while in some cases the ridicule is warranted there are many cases where such men are extremely valuable to their companies. Opinions differ as to the necessary qualifications of the person holding such a position, and since the entry of women into this phase of our industrial world, many former opinions have been rudely shattered.

We know of one purchasing agent, who upon receiving a shipment of goods went to the forman and said: "I say—I have just received a miscellaneous collection of highly polished brass objects, some with threads on the exterior, others with threads on the interior, while some again have absolutely no threads on them whatsoever." Needless to state this purchasing agent was an Englishman, and upon investigation the goods were found to be some brass nipples; some brass couplings, and last of all some ordinary polished brass pipe. This is not a fanciful tale concocted for the occasion, but is an actual happening. The worth of such a man as a purchasing agent, supposed to guard a concern's expenditures, is self evident.

Another concern we know of engaged a young lady who not only acts as stenographer, private secretary and bookkeeper, but purchasing agent as well. Contrary to the thought that is apt to spring up in one's mind, this concern is not a one horse affair, but a recognized business establishment that handles a large volume of work yearly. The position of purchasing agent has been reduced to a science in this case, and this young lady we speak of is thoroughly conversant with the needs of the factory and office. She keeps in constant touch with the market situation; knows what she ought to pay for the different materials, and in the event of the price not being correct, can prove to the would be seller, that his figure is too high. There is no need for bargaining.

These two examples will suffice. The question remains: "What qualifications should a purchasing agent hold?" To our mind he should be able to procure for a firm the best goods at the lowest posible market price. He should know the ins and outs of railroad work, should be able to push shipments along, and should at all times be conversant with the actual stock an hand.

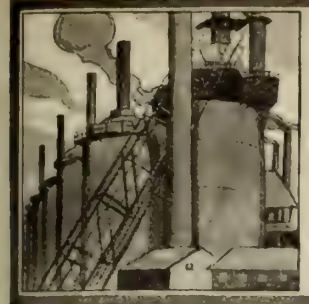
He should if at all possible, become familiar with the shop's routine and plan of manufacture, for in this way he may discover leaks in efficiency. He should not merely be a desk executive. By this we do not infer that he should serve his time at the machinist's trade for this is unnecessary. There is just as much danger in such a procedure as there is in the other extreme. A purchasing agent must not be unduly influenced by the foreman's views. He should consider the foreman, but only as a part of a smooth working machine. He must attend to the daily wants of the factory, but if in his opinion, the system of requesting material is not satisfactory, he should openly discuss the situation with the general manager.

The task of purchasing agent, if handled correctly, requires tact. One cannot purchase from every concern and enemies have been known to cause friction. A record of all orders placed should be kept, prices, conditions, etc., being checked upon the same. We could go on indefinitely pointing out things a purchasing agent should do, but we will conclude with something he shouldn't do—viz., tell the manager his business—until he gets to the point where one manufacturer we know exclaimed "that Purchasing Agents were only men who had failed to make good at their ordinary clerical duties."

An Important Decision

THE recent decision of the British Government to abandon their lighter-than-air craft will come as a distinct blow to those interested in this phase of air service. The present program is sweeping in its intention and calls for the scrapping of all airship stations, existing airships, and ships in process of assembly.

According to those who wish the service continued, the decision has been reached just at the point where the business has become efficient. This viewpoint, however, is more than likely to be very one sided, as naturally the men engaged on such work, wish it to continue. There is only one true method of arriving at a decision in a matter of this kind. Inspect the cost sheets; see what they show, and if the value received in service does not in some small measure vindicate the existence of such craft, then by all means scrap the service.



It may be a bad blow to aeronautics, but not so bad as would appear at first glance, for the decision only affects one section of the science. We still have our heavier than air machines which have proved of such value that there is not the slightest possibility of eliminating them. The money saved on the scrapped section can probably be devoted to the development of the other service with more satisfactory results.

Distilled Destruction

CAN YOU picture a poison so deadly that three drops placed on a man's skin will cause death? From Washington comes a report that the chemical warfare service of the United States have perfected such a fluid. It is claimed that 4000 tons of this fluid will wipe out 1,000,000 men, and that it will be possible to drop this death spreader from aeroplanes overhead.

The science of chemical warfare has certainly improved within the past five years, thanks to our past great war, and if those in charge of such departments all over the world keep on experimenting, they may yet succeed in making war such a horrifying business that nations will be afraid to start one.

In the days of Nero and Alexander, strength was the main factor in war, but at present victory goes to those nations possessing scientists with the greatest capacity of visualizing and perfecting horrors to inflict on the opposing forces.

MARKET DEVELOPMENTS

Expressions of Opinion Vary Considerably

The Market Shows Signs of Improvement, Although There Is a Tendency to Wait for Still Lower Prices—Steel Mills Operate at Greater Capacity—Railroads Are Possible Customers

THE observer who maintains an unbiased attitude cannot help but admit that the demand upon the steel market is slightly increasing, while on the other hand, prices are tending still further downward. Those who say there is no improvement, confess, when cross-examined, that there is at least some slight improvement, although as they say, it's not enough to do any good.

Some salesmen are complaining about present prices, saying that their customers will not take hold until prices are considerably lower than they are now. Others say that buyers are only taking what they actually require, and would not buy any more no matter what the price.

The middle of July can be safely said to have been the turning point in the steel market, as since that time improvement has been noted. True, the improvement is not very great in some lines, but others again have improved considerably, the greatest of all being sheets. From 30 per cent., on the part of the leading interests, and 15 per cent. for the independnets, the operative capacity of the steel mills has increased to 40 and 25 since the middle of July.

Although a wide open, competitive market in steel products exists, prices are not being slashed, nor can they be said to be in a regular course of decline. They sag now and again at one point or another, but it is quite certain that the market is not going to break any more.

The prospects in railroads are bright, and if present plans go through, the railroads will have money to pay their accounts and have something left over to spend on improvements.

PITTSBURGH, August 11.—As to the volume of demand upon the steel the steel market is slowly stagnating upward. As to prices, it is slowly stagnating downward. The observer who endeavors to maintain an unbiased frame of mind and watches conditions carefully can easily convince himself that these two trends do exist unmistakeably, also that the movements are very slow. Members of the trade exhibit the usual temperamental differences in their expressions as to the market Some express the greatest cheerfulness over the changes which have occurred. Others deny that there has been any improvement, but when cross-questioned have to admit that there has been what can be called an improvement, while they then insist that it is not enough to do any good. Steel salesmen who are anxious to see a big turnover complain about prices, saying that their customers will not take hold until steel prices are considerably lower. Those who are content so long as things are moving in the right direction instead of in the wrong direction, as they were for at least nine months, say that buyers are taking only what they absolutely need and cannot get along without, and would not buy any more no matter what the price.

There is more in this divergence of feeling than appears on the surface. There is a question involved, whether the old style of steel market movements is to be followed in future, or whether there is to be a new style of doing business. According to the old style prices would recede and recede until a level was reached too low to be permanent, and then a "buying movement" would start, jobbers and manufacturing consumers taking hold for forward deliveries because they expected prices to advance, filling the mills with specifications and laying in stocks because they expected the mills to fall behind in deliveries.

To many, however, it seems improbable that any such movement is going to occur. These others think the productive capacity is so large, and the mills are giving such good service in deliveries, that buyers will see no occasion to stock up, but will buy from time to time just as their requirements dictate, and that the mills, foreseeing such a condition as likely to last for a long time, will be careful not to let prices go down too far, lest they could not be gotten up again. If the steel market moves according to this style, it will not go down much more in the near future, but as time passes and costs can be reduced, it will sag a little at intervals.

Demand Broadening

The turn in the volume of demand upon the steel mills can be definitely set for about the middle of July. Some lines may not have improved noticeably since then, but they have not lost ground, and some lines have beyond question improved very considerably. The greatest improvement has been in sheets. At the middle of July the leading interest was operating at less than 30 per cent, and the independents at only about 15 per cent. In the past week the leading interest has been doing more than 40 per cent and the independents at least 25 per cent. The operations are a precise measure of bookings, whether of new orders or of specifications against contracts, most of the leading interests' business being of the latter character, for substantially all the business placed is for the quickest shipment that can be made. Tubular goods come next in point of improvement and merchant steel bars third. Rails are at the bottom of the list, being dead.

In some quarters there is reference to "improved sentiment" and all of that sort of thing. This is thinking in the past. There is no sentiment at all in this market, of one kind or another. Anyone these days who places an order or a specification does so because he knows he can work off the material at a profit and get his money. He has "confidence" in that, and is not trying to have confidence or avoid having confidence in the future of steel prices but simply expects to buy at the best price possible when he again has occasion to buy, which may be in a week, a fortnight or a month. It is plain, sound, substantial business.

Steel Prices

There is a wide open, competitive, market in steel products, and has been for several weeks. Prices, however, are not being slashed and can scarcely be said to be in a regular course of decline. Rather, they are

sagging now and then at one point or another. The market presents all the more appearance of stablity when there is open conpetition and yet so little happens. It is quite certain the market is not going to "break" any more. If there were going to be another break it would have occurred already. A break would have to be several dollars a ton. On carload lots bars are 1.75c and shapes and plates 1.85c. Possibly 1.60c has been done on some very attractive orders. If not, it is probably because orders sufficiently attractive have not appeared yet. It seems plain that prices could not go to less than 1.50c in conditions likely to obtain in the next few months.

These products went at 1.00c or 1.05c late in 1914. and that appeared to be an irreducable minimum. The freight rate advances since then add about $6 a net ton to the heavier finished products and say $8 a ton to the lighter, like tin plate, which requires a great deal of coal in its manufacture. Wages are likely to be on the basis of 30 cents for common labor, against 19 cents in 1914, and that means nearly if not quite as much as the freight advance, so that 1.60c would be approximately as low a price for bars, shapes and plates as 1.00c was in December, 1914, and that was extremely low. If one-third of the freight advances are taken off a few months hence, and the reductions will hardly be as much, that would be only about $2 a ton.

On attractive orders black sheets can be had at 3c and galvanized at 4c, representing declines of about $5 a ton in the fortnight, easily the heaviest decline in any part of the steel market.

Prospects

Railroads are doing more car repair work, particularly in the repair of box cars against the grain movement that will be heavy in a couple of months. Plans for putting railroads in good financial condition, recently matured at Washington, are going through. Railroads will soon be able to pay their accounts and will have something left over for improvements, while their earnings are increasing month by month. They will probably buy with some little freedom before the end of the year, and this will help business generally. The liquidation of stocks of steel and of manufactured goods is proceeding, the progress already made being the chief cause of the improvement in mill demand already witnessed. Labor and financial conditions are improving and in time this improvement will doubtless result in more construction work being undertaken. Henceforth all the trends affecting the demand for steel will be favorable, although the improvement will be quite gradual.

A sale of 2000 tons of basic pig iron has been made at $18, valley furnace, or $1 below the market as previously quoted. Bessemer is offered at $20, valley, or 50 cents decline. Foundry remains nominally at $19.50, valley, but on a firm bid the price could doubtless be shaded.

POINTS IN WEEK'S MARKETING NOTES

The demand on Steel is stagnating upward, while prices can be said to be slowly stagnating downward. Both movements are very slow.

Some dealers are cheerful over the change in the steel market, while others deny there has been any improvement. The latter when cross-questioned have to admit however that a certain amount of improve ment has taken place.

Salesmen, anxious to see a big turnover complain about prices.

They say that until steel prices are considerably lower their customers will not take hold. Other dealers claim that buyers are taking only what they actually need, and would not buy more at any price.

The turn in volume of demand upon the steel mills can be set for about the middle of July. Some lines have not noticeably improved since then, but they have not lost ground. Some other lines have improved considerably.

The wide open, competitive market in steel products continues. Prices are not very slashed however, but are merely sagging now and then at one point or another.

Wages can be pretty well set at around 30 cents against 19 cents in 1914.

On attractive orders black sheets can be had at 3 cents and galvanized at 4 cents. This representing declines of about $5 a ton in the last two weeks,, easily the heavest decline in any part of the steel market.

Plans for putting the railroads in good financial condition are going through. This means that they will probably buy with some little freedom before the end of the year. This of course will help business generally.

2,000 tons of basic pig iron has been sold at $18, valley furnace, or $1 below the market as previously quoted. Bessemer has a decline of 50 cents.

NEW INSTITUTION HAS BEEN FORMED

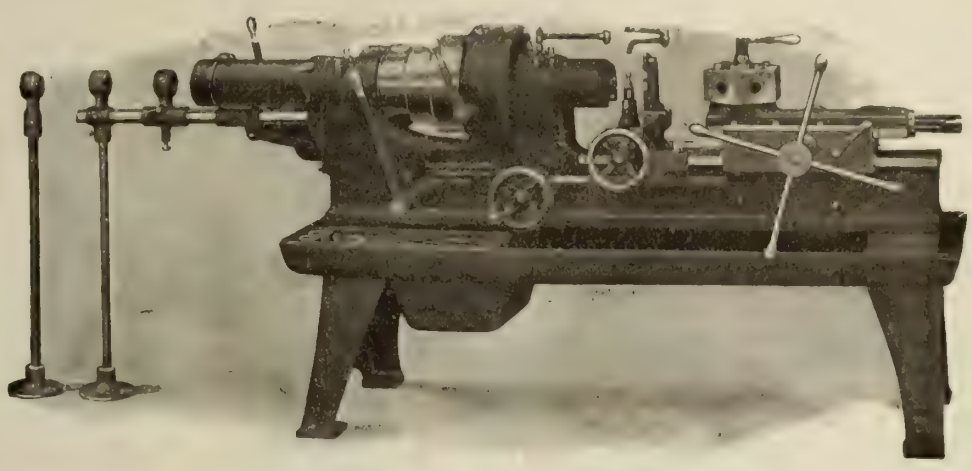
Engineering Trades There Still in Process of Making Their Adjustments

The larger engineering industries are still completing orders taken before the general trade depression took place. As the period between the taking of the order and delivery is always long in these industries, the goods being built to detailed specification, the worst effects of variation in trade are modified.

Advantage is being taken of the quiet period to reduce inflation and to put into operation many schemes for more effective working which have, perforce, been put aside until the present. Some of the more highly paid operatives, finding that their services are not remunerative to their employers, have agreed to substantial reductions, and the falling tendency of the cost of living has materially assisted in the deflation of the cost of labour without serious reductions in what economists call "real wages." The output of the individual workman has improved in correspondence with the ratio of unemployment, and this has made it possible still further to reduce the labor cost of each piece of work. In order to retain skilled workmen and avoid as far as possible the evils of unemployment, employers have co-operated to reduce costs in order to induce orders, and many cases are known of quotations in which profit has been entirely eliminated. These measures are having their effect in pulling the situation round, and many foretell an early return to more prosperous times.

The loom makers, amongst the textile machinery makers, have now reduced prices all round, but the makers of spinning machinery, with one or two exceptions, are not taking fresh orders. It is, of course, obvious that present work on orders booked two years and more ago is being executed at a loss, and the fact that a given branch of the industry is or is not able to quote lower figures bears no relation to the question of profit. In these trades it is well known that those who are not reducing prices are generally suffering from having taken on orders at fixed prices in a rising market.

A committee made up partly of employers and partly of representatives of workpeople in the engineering and shipbuilding industries are making preparations to pay visits to Holland, Belgium, and Germany, in order to study the question of the relation of hours of labor and wages on output. This is a sign of the obvious desire of all parties to return to the normal at the earliest possible date. Such visits can do nothing but good to all who participate in them.



The shipbuilding industry has suffered from a strike of joiners who have declined to submit to a reduction of wages proposed by the employers in order to reduce the cost of reconditioning ships which was sufficiently high to drive orders to Continental yards. The strike has, unfortunately, had precisely that effect, and many contracts have been lost to the country because the shipowners cannot await the result of the strike Further, other grades of workers have suffered unemployment from this cause

A new institution under the title "Institute of Production Engineers" has been formed for the study of methods of production, with a view to improvement in quantity and quality and production, and the first meeting was held on 2nd April Without replacing or duplicating the functions of other institutions it will generally tend to a wider appreciation of the more commercial aspects of engineering, and is expected to assist the adminis

HARD COAL OUTPUT IN UNITED STATES

During the first five months of 1921 the production of hard coal for the United States was 37,700,000 tons net. This figure exceeds any since 1913 with the exception of 1917 and 1918, these latter periods being at the height of the war output. Below is given the production in May by years (in tons net):

Year	May	Calendar year to May 31
1913	7,945,000	38,300,000
1914	8,348,000	35,600,000
1915	7,807,000	35,200,000
1916	7,212,000	36,100,000
1917	8,933,000	39,500,000
1918	8,880,000	41,200,000
1919	7,525,000	32,500,000
1920	7,946,000	36,100,000
1921	9,497,000	37,700,000

WAGES IN GERMAN METAL INDUSTRY

Some wages are as high as 800 per cent over 1914. To offset this it is claimed the cost of living has increased 1,550 per cent since 1914 in some cases.

The Union of German Metal Workers is the largest trade-union in Germany and includes more than 1,600,000 members. This union has a statistical bureau which has collected statistics of wages and of cost of living in the metal industry, including in its investigation not only the members of its union but many other workers in the metal industry, so that the investigation covered a total of about 2,300,000 workers. It has published the results of its investigation in the Metallarbeiter, which is the organ of this union.

According to "Commerce Reports," the statistics of this union show that about 63 per cent of these workers are receiving wages which are more than 800 greater than those of 1914, about 36 per cent are receiving wages which have not increased as much as 500 per cent since 1914. It is impossible from these statistics to arrive at an average increase for the whole of this group of workers.

The trade-unions estimate that the entire cost of living for a family of four has increased about 1,550 per cent since 1914, while Calwer's Bureau (a private statistical bureau), which usually makes use of official statistics, estimates that the cost of food alone for a family of four has increased about 1,470 per cent since 1914.

H. T. Day, Mirrlees, Bickerton & Day, manufacturers of the Mirrlees Diesel Oil Engines, is in Canada on an extended tour. During the course of his stay Mr. Day will visit and inspect each installation made by his company.

TRADE GOSSIP

The F. Bowden Lumber Co., Toronto are contemplating building a planing mill in the near future.

Fire destroyed the warehouse of the Standard Vinegar Co., at Calgary, Alta. recently, the loss being around $30,000.

If present plans go through, Port Stanley will have a modern summer hotel, which will cost around $150,000.

The Empire Cotton Co., Welland have added some three hundred hands, and are now working a night shift.

L. E. Simoneau, 422 Rue Richmond, Montreal has commenced making electrical appliances.

The Galt Amateur Athletic Association, Galt, Ont., are going to erect an artificial ice rink at a cost of $100,000 if things can be properly arranged.

Labor will be paid at the rate of 40 cents per hour, on the Chippewa development scheme, this new rate having started on Aug. 8th.

The Massey Harris Co., Ltd., Toronto, Ont., closed its plant the other day. No definite date of re-opening has been announced as yet.

According to the "Canada Gazette" Pitt Railway Equipments Lted, has been incorporated with a capital of $100,000. This company will carry on the business of electrical engineers and contractor dealers and the head office is to be in Montreal.

Another company which has incorporated is the Continental Electric Co., Ltd. This company will have their head office at Toronto and is capitalized at $40,000.

The Lorne Tractors Ltd, will establish a factory in Chatham. A large tract of land has been secured, and this company intends broadening out considerably.

According to the decision of Judge Kelly at Osgoode Hall, Toronto the other day, the lands and buildings at Brantford, valued at $376,000, and occupied during the war by Motor Trucks, Ltd., belong to the United States Government.

A certain firm starting in Ontario, would like to get in touch with firms handling polishing lathes, drill presses, punch presses, grinding stands, nickle stands, anodes, and dynamo, also a 10 or 25 h. p. motor. These could be either new or second hand. W. G. Astle, 154 W. Haseltine Ave., Kenmore N. Y.

HANDLING ENGLISH LINES.

The Canadian Fairbanks-Morse Co Ltd., Montreal, Toronto, etc., are handling the "Allen" line of engines an pumps. These pumps are manufacture in England, and the concern producin them also manufacture a full line of en gineering specialties.

Following is a list of the bulletin procurable through the Canadian Fai banks-Morse Co., at any of their office Oil engine driven pumps, electric moto driven pumps, pumping machinery, stea engine driven fans, steam turbine drive fans, steam turbine driven pumps, stea engine driven pumps, steam turbi driven generators, steam engine drive generators and oil engine driven gene ators.

These are also obtainable: Gener machinery, high-efficiency condensi machinery, surface condensing machi ery, high-efficiency surface condensi machinery, high-efficiency surface co densing plants, description and illustr tions of condensing machinery, gene description of machinery, electric moto and control gear, enclosed forced lub cation double-acting engine and contin ous current dynamo, open double-acti steam engine and continuous current d namo.

PART OF ACT HAS BEEN REPEALE

The British Government has decided abolish the Agricultural Wages Boa The first part of the agriculture a which became effective six months a will be repealed, and agriculture will completely decontrolled. This means end of minimum wages and Governm control of methods of cultivation.

It is understood, states Trade Comm ioner Wilbur J. Page, at London, E land, that the repeal of the first part the agriculture act is due to the financ crisis through which the country is pa ing. The decontrol of agriculture been under consideration for some ti but the coal strike precipitated devel ments. It is expected that the Wa Board will continue to function for su ient time to allow necessary adjustme to take place.

In the July 21st issue of Canadian M tirely decontrol agriculture. The gu antees for wheat and oats will go w the present crops are harvested. Wages Board will ultimately go, as as all cultivation orders, including powers possessed by county council enforce proper cultivation. This leave nothing in the agriculture act cept the clauses giving security of ten

WATCH THIS

In the July 21st issue of Canadian M chinery we presented a further talk Ralph E. Flanders on the machining pump rod. Of course it will be un stood by readers that the time 'c minutes and 32 seconds given in article was for the first operation c as that was the only operation under cussion.

It Was Just A Matter of Grinding

The same set of Thread Chasers cut these two threads.

Observe what a clean cut the Chasers gave on this open hearth stock after they had been correctly ground. Note how neatly the Chasers curled out the chip. Before given the right form of grind, the Chasers simply pushed out the stock.

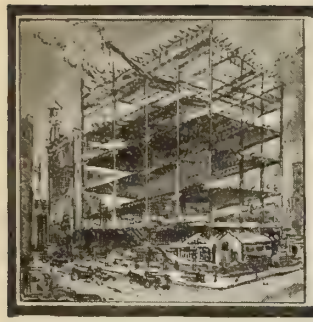
How To Grind Thread Chasers

Instructions for the Care of Thread Chasers are very completely given in a 27-page booklet published by us.

The Book Is Free

To those having the care of Thread Chasers.

It is printed and distributed with the hope that the rules given will be followed, and if they are, it will be the means of an inestimable saving of time, money and trouble.



If you have anything to do with the care of Thread Chasers, ask us for the book. Although there is no charge for the book, it is full of value. It will cost you the price of a postage stamp only, and will save you trouble, increase your value to your employer and save a lot of money that is needlessly wasted in time and scrapped work.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

WASTE IN WAGES IN BUILDING INDUSTRY HALF BILLION YEARLY

IT SEEMS strange how waste can accumulate so rapidly, but the recent figures issued in the report just made public by the American Engineering Council's Committee on Elimination of Waste in Industry are not only strange and surprising, but actually alarming.

According to the report half a billion dollars a year in wages is being lost in the building industry through unemployment. Lack of work is said to be the outstanding factor in this industry, and the condition is attributed to present high cost of construction.

Without going into the report in detail, here are some of the items mentioned: The chief sources of waste in the building industry are, according to the report, irregular employment, inefficient management and wasteful labor regulations. Customs or conditions prevailing throughout the industry and poorly designed equipment are given as secondary causes.

The annual economic loss due to accidents is estimated as high as $120,000,000. Application of safety methods, it is stated, would save to the industry 12,000,000 days a year.

Some Causes of Idleness

"The building trade workman," asserts the report, "is busy on the average about 190 days in the year, or two thirds of his time. A few contractors, individually or associated, are attacking this problem with effective results. The public also must be educated to the need of a sensible distribution through the year of its construction demands and requirements. Idleness, however, is due not entirely to seasonable demands; strikes and lockouts are appreciable causes.

"Haphazard management in planning and controlling work, and lack of standards, which often double the labor cost, characterize most construction undertakings. Here, again, a few builders, recognizing the waste in money and man power, are adopting methods that approach modern factory management.

"In some construction trades accidents involve losses up to ten per cent. of the labor cost in addition to the human loss of lives and energy. The average loss, computed from insurance statistics, is about two and one-half per cent of labor cost. Here also certain contractors have found it possible to cut their accidents in half through special efforts. Greater co-operation between the workmen and the employers is an absolute essential. This co-operation must be attained before we can approach the elimination of labor difficulties.

Inefficient Management

Inefficient management is blamed for failure to furnish continuity of employment; failure to plan work in sufficient detail; lack of proper schedules to allow proper co-ordination of scheduling, purchasing and delivery with job requirements, lack of standards and adequate cost methods as a means of checking productions; high labor turnover; failure to use proper amount or type of equipment; general failure to develop and use a greater amount of mechanical equipment; and waste of material through careless handling and improper plant operations.

According to the report the number of strikes and lockouts in the building trades increased from 302 in 1914 to 452 in 1919, an increase of 50 per cent. This increase is accounted for in part by the greater demand for labor in 1919, which inevitably makes the requirements of workmen more exacting and arbitrary. Of the 1919 figure, 452, only 18, or four per cent. are listed as lockouts, so that the waste due to lockouts is relatively small.

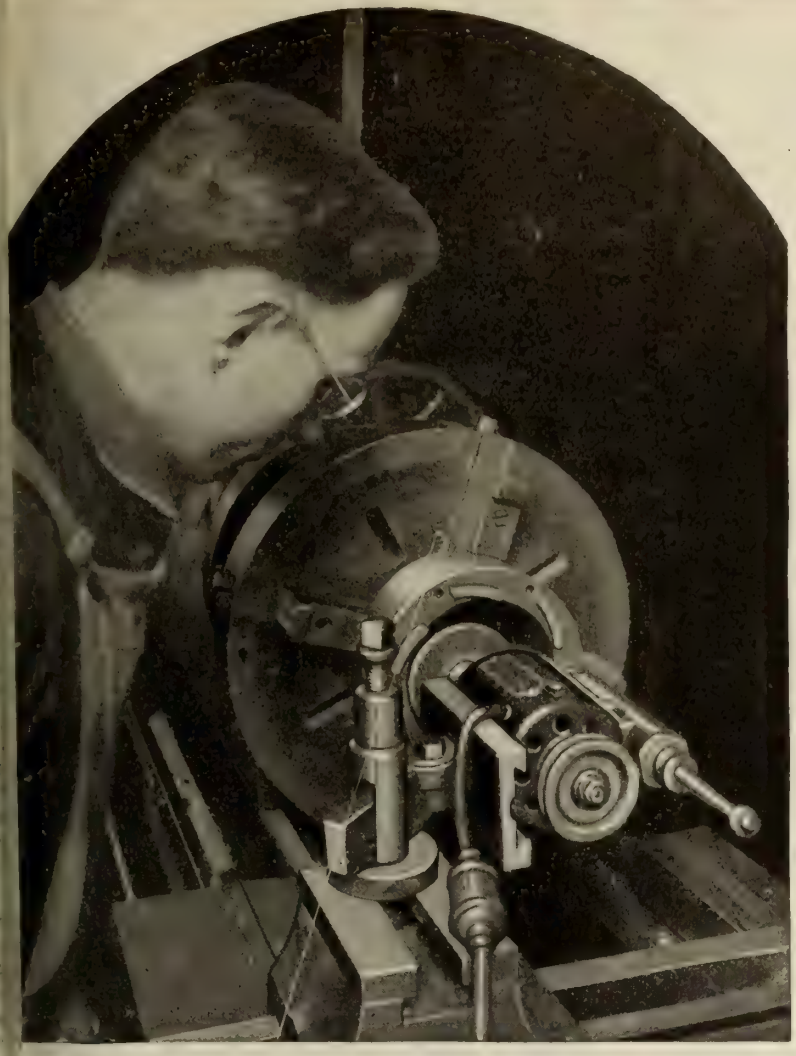
"If the greatest cause, the demand for an increase in wages, could be eliminated, strikes as a factor of waste would shrink into insignificance. The remedy that suggests itself is co-operation. Management and labor must forget the sore spots of past conflicts and through whole-hearted co-operation fix by proper studies a minimum wage to correspond with a standard amount of production, with additional compensation for additional output. This would furnish an incentive to the men and would give recognition to deserving mechanics.

"Unions must co-operate to the extent of eliminating the flat rate for all mechanics of a trade, and to the extent of modifying the restriction that forbids mechanics to accept piece work. With definite standards fixed and with the co-operation of both parties, fair incentives can be introduced.

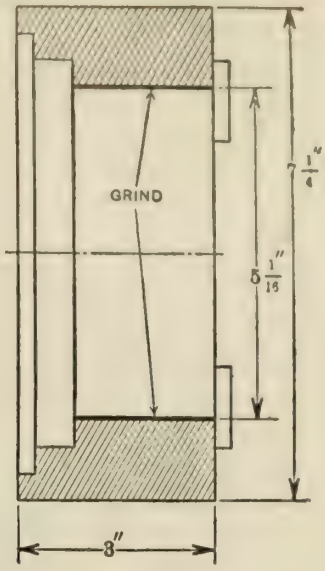
"The most encouraging sign in the elimination of the above causes is found in what is known as the "Philadelphia Plan," put forth by the labor element of that city."

This plan concentrates into a single body, through associations, groups or committees, of each employing branch of the building industry, in number at least equal to the nineteen represented in the council of the Associated Building Trades. A heading-up committee composed of an equal number of representatives from the groups of employer and employed would constitute the tribunal or council of the building industry in Philadelphia. The plan purposes the establishment of a central bureau through which voluntarily all construction programs in the territory should be cleared including national, state, municipal and private work.

Accident Loss



Enormous losses are suffered through accidents, the $30,000,000 paid yearly to insurance companies for compensation and liability insurance by no means representing the total lost, according to the report, which adds:



"In the opinion of one of the best authorities in the country the actual cost of insurance represents not more than 25 per cent. of the total economic loss which brings the total cost due to accidents in the vicinity of $120,000,000 per year, a staggering total."

In Massachusetts during one year accidents caused a loss of time of 485,48 days. In New York State, where four times as many workers are employed in the factories as are employed in building and construction work, there were more fatalities due to accidents in building than in factories during a four-year period. Accidents, it is stated, are largely caused by carelessness of the workmen or lack of ordinary safeguard Conditions which would not be tolerate in a factory for 24 hours are found o every job, it is asserted.

Great savings are possible, says th report. "An official of a large insurance company believes that by prope safety measures the waste due to acc dents can be reduced 75 per cent. to 8 per cent. in from two to five years honest effort, and that constructio labor cost can be cut three per cent. b these measures. Another official est mates, from actual accomplishment safety measures, that a total of mo than 12,000,000 days a year could b saved the industry by the applicatio of safety methods."

The most encouraging feature in th building industry concludes the repo is the action of a few builders and a fe groups of building trade workmen making intensive studies of the caus

CAM
FOR DIE HEAD

Attached to the toolpost of the engine lathe on which this cam has been machined, the Dumore Grinder accurately grinds the hole without necessitating another "set up." The high efficiency standards of the Geometric Tool Co. (New Haven Conn.) make comment unnecessary on this method of handling the job. It is sufficient that the work of the Dumore is so satisfactory, the finish so fine, that all cams this size or larger, made in this shop are ground in this manner.

The Average Shop Has Constant Use for Dumore Grinders

Dumore Grinders are made in types and sizes that can be attached to all classes of machines and used to successfully perform a wide variety of grinding operations.

Equally valuable for the important "odd jobs" that must be done in every shop and on some manufacturing work, they find a ready place in every part of every metal working plant—whether toolroom, factory or repair shop.

Ask us about DUMORE Grinders—full details on request.

Wisconsin Electric Company

2938 Sixteenth Street **Racine, Wisconsin**

DUMORE HIGH SPEED GRINDERS

and remedies for irregular employment and haphazard conditions of work. Along with this is the growing appreciation on the part of both labor and management that to build more buildings and maintain high wages, it is necessary to attain greater and greater productive capacity per man.

"They see as proof of those facts that the 1921 depression was caused and extended by too high costs of all products, and that business, either in manufacturing or in building industries is improving only as the costs of material and the cost of labor are reducing. All are recognizing, in fact, that no progress can be made without paying greater and greater attention to the elimination of waste.

CHROMIUM DEPOSITS IN VARIOUS COUNTIES

Canada Has Increased Output from 121 Tons in 1914 to 33,000 in 1917.

India Also Had Large Increase.

Speaking on the importance of Chromium in the steel industry, a writer in "The Near East American" tells of various places where such a material is found. He says that originally large supplies were obtained from the deposits near Brusa, Asia Minor, the production of chromite in 1908 having been 29,000 tons. Later, Southern Rhodesia, and New Caledonia became the chief sources of supply, and in the pre-war years the German steel industry used to draw upon Asia Minor. The inquiry for chromite was stimulated by the war. Canada, which had an output of 121 tons in 1914, soon produced 33,000 tons in 1917, while India increased her output of 5,888 tons in 1914 to 57,773 tons in 1918. The Indian deposits are scattered over several provinces. The mineral has been found in the peridolite rocks of the Chalk Hills near Salem, Madras, and also in the Andamans. Another deposit area occurs two miles east of Yhamogia, in the Pishin district, and it consists of a rich veinlike mass with 54 per cent. of chroms oxide. Good supplies are also available in the districts of Mysore and also in Singhbhum, Behar. The regions have not been well exploited. In July 1914, the Beluchistan Chrome Company, Ltd., was registered in England to acquire leases of chrome areas covering 6,159 acres in the Hindubagh district of Beluchistan. A railway from Khanai to Hindubagh has been constructed, and the shipments commenced in March 1917.

The Adanac Motor Syndicate has been formed at Lachine, P.Q. This company intends manufacturing motor trucks, and has produced its first sample truck. The present organization is composed of Messrs H. Milton Purnell, Gordon A. Emslie, B. H. T. McKenzie, B. A. Malkin, Robert Connon, H. Emslie, and A. T. Sutherland.

FRENCH EXHIBITION TRAIN WILL TOUR DOMINION WITH EIGHT CA S

SOMETIME about August 25th, an important French delegation will arrive in Canada. The purpose of the mission is to inaugurate the made-in-France sample train, which will tour the Dominion at a later date. This train will constitute an exhibition on wheels, composed of eight different departments—manned with a competent personnel travelling with the train and living in the sleepers and diner provided for their comfort. The eight exhibition coaches will each present some special products of France prepared and exhibited under the patronage of distinguished personalities.

Eight Cars

The first car, entitled "La Pensee Francaise"—the French thought; comprising literature, science and arts—will be under the presidency of Mr. Raymond Poincare, Senator and Ex-President of the French Repbblic. The second car, entitled "Industry, Commerce and Tourism," including transportation by land, sea and air, and civil and mechanical engineering, will be under the presidency of Mr. Dal Piaz, President of La Compagnie Generale Translantique, commonly known as the French Line.

The third car, entitled "Fashion, Tissues and Laces, etc," will be under the presidency of Mr. Auguste Isaac, Member of Parliament, Honorary President of the Chamber of Commerce of Lyons, and Ex-Minister of Trade and Commerce. The fourth car, entitled "Leather Industries," and ranging from the raw material to the glove and highest grade product, will be under the presidency of Mr. Poullain, President of the General Association of dealers in skins, hides and leather, of France.

The fifty car, entitled "Chemical Products, Drugs, Pharmacy, Perfumery, etc." will be under the presidency of Mr. Amic, Senator, and Vice-President of Le Comité Francais des Expositions. The sixth car, entitled "Articles de Paris, scientific instruments, etc., will be under th presidency of Mr. Emile Dupont, president of Le Comité Francais des Expositions.

The seventh car, entitled "Agriculture, Horticulture and Foodstuffs," will be under the presidency of Mr. Albert Viger, President of the National Association of Horticulture of France, ex-Minister of Agricuuture. The eighth car, entitled, "Jewellery, Objects of Art, etc.,, will be under the presidency of Mr. Paul Templier, President of the Jewellers and Goldsmiths of Paris.

It is expected that the train will be at the Toronto Exhibition for the duration of its run, but in addition to this, practically every important centre will be visited and the public given full opportunity to view the exhibits.

A tentative itinerary has been arranged, covering the following cities and towns: Montreal, Joliette, Shawinigan, Three Rivers, Quebec, Sherbrooke, St. Hyacinthe, Thetford, St. Johns, Valleyfield, Ottawa, Brockville, Kingston, Belleville, Peterborough, Toronto, N g- ara Falls, St. Catherines, Ham n. Brantford, Woodstock, London, Win r. Chatham, Stratford, Kitchener, Guelph, North Bay, Sudbury, Soo, Arthur, Fort William, Winnipeg, S toon, Edmonton, Banff, Kamloops, couver, Victoria, Calgary, Lethbr Medicine Hat, Swift Current, Moos Regina, Brandon, Winnipeg, Coch Cobalt, Ottawa, Montreal.

Concurrently with each stoppa suitable theatres, moving pictures display special goods and striking i trial processes. The circuit conten ed will cover over 8,000 miles, and e over a period of more than two m

Upon its completion the exhibit be placed in the museum hall o school for high Commercial Educ in the City of Montreal, and r there upon a fixed exhibition for ar six months, in order that the exhi after such a rapid journey throug land may have an opportunity to lish agencies, tie up solid commerci lations, and form the nucleus of a tele which it is hoped will grow time.

QUALIFIED MEN SHO DEVOTE TAL

In the opinion of Edwin S. Ca president of the American Society o chanical Engineers, it is throug fulfilment of the concept of "Serv Others" that engineers have won t teem of society at large. He say this is a mechanical age which pr opportunities to the engineerings p sion such as never before existed.

Mr. Carman who has recently pleted a series of visits to the A. Local Sections, said that the opp ties now before the engineering p sion can only be completely re "when they all work together as a with one aim in view, that of Se

After touching upon the incre membership, he mentioned that th gramme of service to be rendered American Society of Mechanical eers can only be accomplished a joyed to the fullest extent by the participation of the individual m There are still many qualified men mechanical engineering professio cording to Mr. Carman, who are devoting their talents to anythi yond the small circle in which th engaged, not yet having fully r the advantages accruing from asso with their fellow engineers and ing of "Service to Others."

The Canadian Westinghouse Co Hamilton, Ont. have taken on few new men in their Shur Air Dept., as this section is rathe at present. They have the ord the air brakes for the 200 new T street cars.

DIFFERENCE IN PRICE WOULD BE SMALL

Farmer buying power affected by recent drop in farm produce. Bulk of goods of this concern outside their control.

Speaking on the subject of the recent closing of the Massey-Harris Plant at Toronto, Mr. Thomas Bradshaw, general manager of the plant, states as follows:-

"Our country, in common with all others dealing with the farming community, has been greatly affected by the sudden and heavy drop in the value of farm produce. The farmer, not knowing all the conditions, has had the feeling, perhaps quite naturally, that manufactured articles should drop correspondingly in price with this produce. Such has not been the case, and this has prevented buying in some instances where it would be to his advantage to do so, even at present prices. We are quite sympathetic with the policy that he should buy what he really needs under existing circumstances.

"We did not expect normal sales in 1921, and made our plans accordingly. We did feel, however, for all the difference there was in the price of implements this year and the probable prices next year, that no farmer could put off the buying of an implement really needed, because the difference in price, spread over the life of the implements, would not amount to much.

"The bulk of the cost of the goods is quite outside our control, and, while a great deal of labor is involved in the cost, it comes to us in the form of materials. Such reductions in material costs as took place in our manufacturing season came too late to be of any help. The farmers, as are all our customers, are perfectly justified in demanding a reduction in the cost of manufactured articles, but this cannot come so abruptly as in the case of the drop in the value of farm produce because the channels through which it comes are so extended that it takes more time to make adjustments.

"Wages must come down, but great hardships would be caused by too sudden a drop, and we think the consumer should recognize this and give labor time to adjust itself to new conditions. Freight rates are a big item in costs, and there has been no adjustment along this line yet."

THINGS IN ENGLAND ARE PICKING UP

"Things in England are beginning to pick up, and from what I can see our revival is reflected in Canada." This is the opinion of H. Wickman, seed editor of the London Times, who is at present with Lord Northcliffe on his tour through United States and Canada.

According to the speach, the Pacific conference to be held in Washington will have far reaching results. Speaking of German trade he says that it has revived to any great extent. The change rate is against this, and there is less German produce coming into gland to-day than there was a year The existing rate of exchange ma it impossible for the Germans to re their trade to any great extent."

LARGE WATER POWER IS AVAILABLE HE

The water power actually avail in the Dominion of Canada has rec ed close attention of the Dominion ter Power Branch during the past years. A careful re-analysis and c putation of such resources have systematically collated, analyzed, co-ordinated with a view to prepa on a uniform basis from coast to c revised estimates of the power a able. While the analysis is not yet nally completed , sufficient prog has been made to warrant publica of the figures following:

The recorded power available thro out the Dominion, under conditions ordinary minimum flow is 18,255 h.p. The water power available u estimated flow for maximum deve ment i.e., dependable for at least months of the year is 32,076,000

There are installed throughout Dominion water wheels and turbine the extent of 2,471,000 h.p. Howev it would not be correct to place figure in direct comparison with minimum or maximum available po figures quoted above and therefrom duce the percentage of available w power resources developed to date. allowance must be made for the ave ratio between the water wheels insta and the power available.

An analysis of the water po plants scattered from coast to c concerning which complete informa is available as to turbine installa and satisfactory information as stream flow, gives an average mac installation 30 per cent. greater than six month flow maximum power. plying this, the figures quoted a therefore indicate that the present corded water power resources of Dominion will permit of a turbine stallation of 41, 700,000 h.p. In o words, the present turbine installa represents only 5.9 per cent. of the sent recorded water power resources

The total Hydro power developn installed during the past year or under construction represents app imately 560,000 h. p. of installed ca ity. This figure includes only the in installations of plants under const tion not their ultimate designed capa

According to reports the Stand Steel Construction Co., Welland, will resume operations at full capa It is said that some good contracts h been secured and present orders sufficient for at least the next t months.

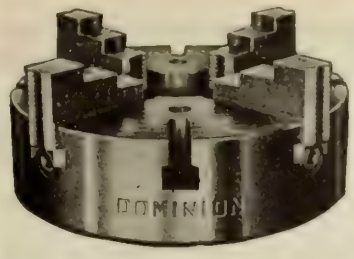
...KING AND SHIPPING

...ontinued from page 32)



...ip companies would give to ex...a mate's receipt for so many ... accepted from the railway ... for shipment. These points ...portant in themselves, but if ...edit would add to the attraction of ...siness with the Dominion rather ... other countries, and would in-cidentally benefit the transportation companies.

There does not appear to be any possibility of improvement in the methods of packing and shipping nails to this country from Canada. On the contrary it is stated here that Canadian nails are packed in a much superior manner to those coming from Germany and Belgium. From Canada they arrive packed in casks and bags, in each case lined with waterproof paper. German and Belgian shippers use no waterproof lining and consequently the nails often reach here in a rusty condition.

TRADE GOSSIP

The Universal Craftsmen Convention, which came to a close in Toronto the other day elected the following officers for the ensuing year:—Grand Worshipful Chief, W. Warfield, Newark; Grand Assistant Chief, J. M. Patton, New York; Grand Warden, G. Brown, Pittsburg; Grand Guard, W. W. Law, Trenton, N.J.; Chairman Board of Trustees, W. H. Damon, Springfield, Mass.; Trustees, E. H. Blade, Chicago; L. C. Cuthbert, Toronto; Grand Chaplain, Patrick Earley, Milwaukee.

The Toronto, Hamilton and Buffalo Rly. Co., Hamilton, are contemplating the construction of a bridge to cost about $30,000.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.
